

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

"LET US HAVE THE FACTS"—No. 12

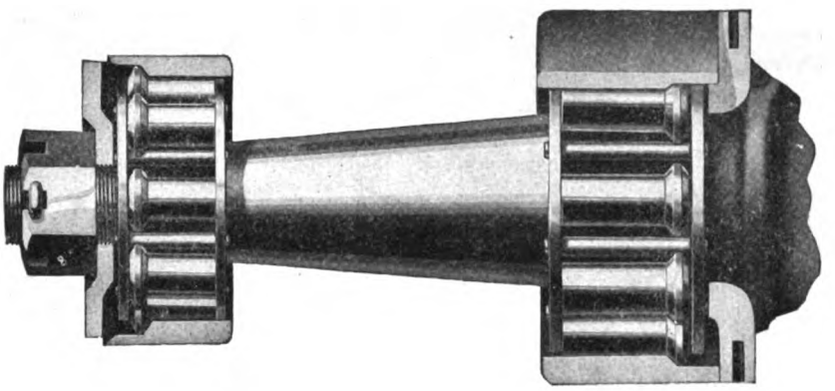
COOLING SYSTEMS

Effective cooling and efficient cooling are by no means one and the same. There is often a difference of from 5 to 15% in operating economy in favor of the latter. It is, of course, imperative that valves should be kept cool—not, however, by keeping other portions of the metal exposed to combustion at a temperature lower than that which makes for highest efficiency.

The BUDA MOTOR

has a cooling system which is unusually efficient. It is provided with a large water jacket space which is so arranged that *the cool water from the pump is discharged directly beneath the valves. This is a very important point.* In addition the design is such that there is free access (by removing one plate) to the water jacket space for easy inspection and cleaning—a decidedly valuable feature.

BUDA motors are developed in every detail—which means a lot to you in the consistent performance of your trucks or tractors.



OUR MOTOR CATALOG IS VERY COMPLETE.

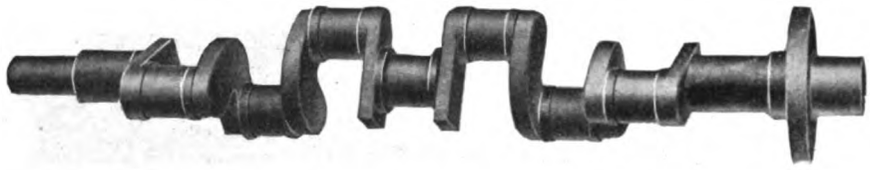
BOWER SAVES POWER

Withstanding the Extra Strain

The front wheel bearings of a pleasure car or motor truck have two distinct thrusts to sustain. First, the downward thrust from the load; second, the side thrust that arises from turns and from the jolts and shocks of rough roads.



Bower Bearings are scientifically designed with a separate surface for each thrust. The downward pressure or "radial thrust" is met by the straight line contact of the roll and raceway, while the flanged head on the roll takes care of the side pressure or "end thrust."

A PROSPEROUS *and* HAPPY NEW YEAR
is assured the manufacturer whose motor is built around the
WYMAN-GORDON
INHERENTLY-BALANCED CRANK SHAFT

THIS crank shaft represents the last word in crank shaft design. Back of this crank shaft, making its production possible, is a fully equipped, perfectly organized plant—one that has not sprung up in a day, but one that has always led in its own field for more than thirty years.

Of special significance is the fact that back of the experience and ability is the willingness to co-operate with the manufacturer who is seeking the best results.

This co-operation is the real keynote of the Wyman-Gordon success. It represents more dollar for dollar value to the motor car manufacturer and more real progress toward perfection than any other one thing.

We should be glad to do for you what we have been able to do for many others.

Efficient Transportation Demanded of Engineers

Sharp Change of Practice Necessary to Eliminate Extravagance of Wheelbase and Engine Size

By J. Edward Schipper

ENGINEERING practice in passenger car work must make a sharp change. The war has brought us face to face with a condition which normally would not have been due for 3 yrs. During these 3 yrs. we would have changed gradually to meet the new state of affairs and normal trends would have carried us through without a break. We have suddenly awakened to the fact that automobiles are not efficient and not economical just at the same time that the people have been awakened by the trumpet call of war to the fact that our daily lives and habits, whether they are concerned with transportation or what not, must be efficient and economical.

The drop in automobile sales is not only because there is not as much money to spend in this country as heretofore, but people are watching more closely the results that they are securing for money expended. People are buying transportation and not automobiles. They measure the expenditure of money for a passenger car by the standards of transportation afforded by the car they buy. They want stability, flexibility, Pullman car comfort, reliability and all the qualities that go to make up good transportation, and above all economy.

Up to the time this country entered the war the people of the United States had been noted as being the most extravagant in the world. There has been a remarkable revulsion of feeling. A wave of economy has arrived. It has exerted its influence in the clothing we wear, in the things we eat, in the places we go to and above all in our transportation. It has exerted itself in the automobiles we buy.

For example: Walk along Automobile Row in any large city and look into the windows of the used car dealers. You see a most significant thing. Big cars which in 1915 sold new for $3,000 and $4,000 are selling for $300 and $400. A depreciation of 90 per cent in 3 yr., and why? Not because the cars are not good automobiles; not because they have not good materials; not because the bodies are out of date, but simply because they are not efficient.

Change in Demand Has Arrived

The extravagance of wheelbase, the extravagance of engine size, the extravagance of fancy metal fittings all built to meet the popular clamor of a public which through the very element of national wealth thought only in extremes. Now a change has arrived. We buy only what we can use. We are no longer patient of wastefulness, our country is at war and conservation must take the place of waste. Unconsciously we have swung around a 180 deg. arc in our national psychology.

This finds the engineering profession unprepared to a large extent. It is true that efficiency in transportation has been in the mind's eye of the engineer for a long time, but he has had to build a car to suit the public as interpreted by the sales department. This is natural enough, as cars must be built to sell.

Digitized by Google

His laboratory work and his engineering discussions have pointed out time and time again that what he would like to build and what the sales departments demand has been exemplified by the difference between sound and unsound engineering fundamentals.

The potential change in the public mind has been sensed but not realized and analyzed by the automobile sales departments, taking the industry as a whole. The drop in sales in certain cars has been interpreted in the commonplace words, "Business is bad," yet business, when transportation is being sold, is never bad. The article sold and the article demanded do not happen to fit.

There have been several clues to this situation. While the business of certain cars in the high-price class has fallen off, the business of other companies in the same field has remained almost at normal. The business of the companies selling lower-priced cars has been exceptional in certain parts of the country and in others has not dropped very seriously. In almost all territories a falling off in business has been directly traced to a tendency on the part of people who changed their cars every year or two, to keep these cars for an additional season or more. It is just another indication of the economy spirit.

Want Economical Transportation

People want economical transportation. If an article is wanted, it makes little difference what sort of a package it is wrapped in, and if the desired article of "economical transportation" comes wrapped in the shape of an automobile, it is not goingto scare away the buyers even though we are at war. Rather, with a universal tendency toward speeding up, it is going to be desired more than ever.

This brings the matter to the engineer. The sales department will quickly adjust itself to the new condition and this demand is sure to fall upon the engineer in turn. In a large measure the engineer is, as a class, prepared for it. If he has been thinking ahead 3 yrs. he is ready at least to logically analyze the problem that he has now before him.

In a large measure it cannot but be a relief to the engineering mind to feel that now a true advance is to be made in automobile engineering. It seems as if the big difficulty of the opposing demands of the public for a big car on the one hand a flexible car with plenty of get-away on the other seems to be passing away. The lesson of the used car just pointed out seems to establish that. The change has been complete even though it is not realized fully as yet by the public.

Where we have been led astray in an engineering way is quite clear. We have been what the public wanted us to be, extravagant. We have been extravagant of wheelbase, extravagant of engine size, extravagant of tonneau, extravagant from radiator to back end, simply to suit a public which asked not what kind of a car, but how much car for the money. Cars have been sold by the pound rather than by their capability of returning to the purchaser the worth of the price in good transportation.

In a great many ways it has been the fault of the industry, which has run with the tide against its better judgment. It is the industry which has led the campaign of high-gear performance, big engine displacement or horsepower, and above all, size.

From an analytical viewpoint we should focus our attention on two matters: wheelbase and displacement. Weight per inch of wheelbase can be materially reduced, it is true, by a scientific distribution of materials and by the use of the best in materials, but it is carrying space per inch of wheelbase, which in other words can also be expressed as pounds of car per pounds of passenger, that is more important. Why should a person buy a car that weighs 7 lb. per pound of passenger weight when it is possible to so design a car that performance will be better and the car weigh but 3 lb. per pound of passenger on a five-passenger car? It must be necessary to show a great gain in comfort or other features before it seems right to take a man's money for a product.

Wasteful Wheelbase

We have been wasteful of wheelbase because we have not economically used space. Every inch of unnecessary wheelbase means unnecessary weight. This in turn requires gasoline, oil and tire upkeep. One typical medium-priced car was shortened 7 in. in wheelbase 3 months ago. The car has equally as much room in the tonneau and 2 in. more room in the front compartment. This is one example of what can be done. It is not necessary to sacrifice space, but to utilize it.

We demand acceleration: To get it with a heavy car means that we must add weight to the engine and this again takes more of all the factors that work against economy. Why is there no real high-priced car on the market with a wheelbase around 112 in? Because the public would expect to see a big car for that money. This condition is going to change. The public is going to demand a car in which it can be shown that every dollar spent brings its return in car value either in direct transportation ability or in comfort. The public is willing to pay for its extra comfort and convenience when it travels by automobile in just the same way that it will pay for its extra comfort and convenience when it travels in a Pullman railroad car.

Explicit directions for shortening wheelbase cannot be given for every make of car because space is lost by different cars in different ways. This is because the wheelbase has been fixed before the car is laid out and is simply utilized because it is there. Almost universally engines are too large. It would be perfectly feasible to secure all the good performance that anyone could demand in a five-passenger car with an engine of 200 cu. in. piston displacement. An engine of this size, regardless of the number of cylinders used, would require but a short hood. Due to its light weight and small capacity the structural members which support it could be correspondingly reduced.

With an eye which was ever watchful to secure the most from every part in the car, to make every part do the duty of two or more, it would not be

Digitized by Google

any great feat to bring the weight of the finished product below the 2000-lb. mark rather than above it. This could be done with plenty of space in the front compartment and tonneau. If the car is to be an expensive one the extra expense will go into comfort and endurance due to the choice of the finest materials and the most careful workmanship. The trimming, upholstery and painting work can reflect the excellence of the equipment and artistry in the vehicle.

Talking Horsepower

Perhaps one of the greatest errors the sales department has injected into the industry is the matter of talking horsepower. It has led indirectly to our use of large engines, whereas horsepower means nothing. It is the combined units of engine torque, gear ratio and car weight which spell the story of performance. The demand for acceleration and hill-climbing ability will always remain with the American public on account of our lack of long, straight, level roads. It is part of the American psychology also to demand that getaway. Attempts to educate the public to gear-changing have failed and probably never will succeed.

Reserve torque is what is demanded and not horsepower, but the exaggeration of the catalog writer has led the layman to believe that if he has an engine of high maximum power under the hood, he has an engine which will enable him to get away faster than other cars which have smaller engines. He does not even think of the other factors of torque, weight and gear ratio.

On page 5 are reproduced some curves which bring out clearly the wide variations in existing types of cars. If these curves are taken as a basis of thought and analysis in connection with the present demand for the ultimate in performance as well as economy the public will part with some of its craving for ultra-long wheelbases and other weight-creating elements. It can have the very kind of transportation it wants with minimum first cost and with minimum upkeep.

There is no doubt that the greatest demand for torque occurs between car speeds of from 14 to 25 miles per hour. The praiseworthy effort to so design the engine that the torque curve rises high and remains flat during this zone, must be continued. The available engine torque is a direct measure of the accelerative power and hill-climbing ability of the car. It is not complete in itself, however, as car weight must also be a factor.

The curves herewith illustrate this point: They show four up-to-date cars, of four, six, eight and twelve-cylinder designs—the actual torque curves of the engines plotted against a speed of miles per hour of the car. These curves show the torques in pounds-feet at the different car speeds and, of course, take in the factor of gear ratio, which would not be concerned were the engine torque plotted alone against r.p.m. In other words, these curves represent the effective torque of the engine at the rear wheels, the size of the wheel also being considered as effecting the final reduction between the engine and the propulsive member.

As a further indication of car performance, these same curves were taken and the weight factor of the car included. The dotted lines illustrate these final curves and are the actual measurement of what can be expected from these four types of cars in definite speed zones.

Probably as interesting a comparison as it is possible to make from the curves herewith given is that between the twelve cylinder and the six. In the actual plotting of torque in pounds-feet, the curve C of the twelve-cylinder engine is higher than that of curve A of the six-cylinder engine for almost its entire length. This would naturally be affected as the displacements are 42.41 for the twelve-cylinder and 288.6 for the six cylinder.

Owing to the fact, however, that the weight of the twelve is more than 1000 lb. heavier than that of the six, 4375 as against 3214, and owing to a slight advance in gear ratio, the indicated accelerative ability of the six surpasses that of the twelve at 19 m.p.h. In the zone between 10 and 19 m.p.h. the twelve-cylinder engine is considerably higher. Thus it would be expected that if high gear were used on both cars the twelve-cylinder car would show a marked advance in get-away at the lower speeds. This is not due to the number of cylinders, but simply to the torque-weight-ratio relationship.

The little four-cylinder engine shown at curve D has an exceptionally flat torque curve and represents what might be called typical effort to secure the highest possible torque as early as possible in the range of speeds. The maximum torque of this engine is reached at a car speed of about 30 m.p.h. At this time about 73 lb.-ft. of turning energy are available. More than 80 per cent of this torque is available at a car speed of only 8 m.p.h.

Torque Curve of Eight-Cylinder

The torque curve of the eight-cylinder engine is another which may be commented upon for its flatness. It is not, however, so flat as that of the twelve or four in lower ranges of car speed. This shows up particularly on the weight ratios. Naturally a direct comparison cannot be made on these four engines from an output standpoint because of the difference in displacement. On the other hand, these series of curves tends to show the difference in torsue to car-weight ratio, and hence gives a direct measure of what may be expected from typical designs.

The connection between the flat torque curve in the early speed ranges and the high-efficiency, high-speed engine has not been brought home. The city driver appreciates being able to throttle down in traffic and at the same time without a change of gear to accelerate up to his speed-limit of 20 m.p.h. This means that the torque curve has got to be high within that range and also that the torque to weight ratio must be high. The terms of engine efficiency and engine ability are often confused. It is quite possible for an engine of low efficiency to have a high ability and the torque curve is no measure of efficiency.

This method of analysis is a key to one of the phases of the situation which confronts us. If it

Digitized by Google

were followed through to its logical conclusion we would have automobiles that are better and which would at the same time bear the relationship to some of our present designs that is best expressed by saying that they give equal comfort with higher efficiency and economy.

War has a purifying influence. It turns the searchlight upon us in such a way that our errors are shown up more clearly than they are in peace times. If we have a national failing in that we are extravagant, let us search out the influence of this extravagance in our best means of personal transportation, the automobile, and bring it up to the level it should be brought to.

It does not seem right, in the face of the struggle we have on hand, to see a little woman weighing perhaps 100 lb. driving alone and unaccompanied a huge touring car weighing more than 2 tons. This is bad economy, it is wasting fuel, rubber, oil, metal, and it is not what we want in any times, much less now. This is only an exaggerated case of what we see every day, but people are not going to keep up buying cars that are as far removed from their everyday needs as this. The car has got to be of the correct size for the purposes to which it is to be put.

Buying Transportation

It will not take long for the sales departments with their fingers on the pulse of the buying public to discover the definite effects of the national wave of economy on car buyers. When the sales department discovers this, it is but a step to the engineering room, and it will not surprise the wide-awake engineer when he is called before the board of directors and asked to produce a car which will wring the last ounce of performance out of every drop of fuel, which will travel the last available mile on its tires, which will have all the get-away and flexibility possible with plenty of room for the occupants, but no wasted wheelbase, no wasted engine displacement and with all the excess comfort and style that the buyer purchases, without having the extra money go into dead weight which has to be carried around to no purpose.

Standardize War Truck Repair Work

Every Repair Job to Be Done by Manual—Even Buildings to Be Standardized

WASHINGTON, D. C., Dec. 29—In line with the general plan for standardization pursued by the transportation division of the Quartermaster Corps under direction of General Chauncey B. Baker comes the new plan of standardization of repair base units for service at home and abroad, by means of which there will be standardized repair shop buildings, standardized corps of mechanics, standardized systems for repair and standardized repair equipment.

What Investigation Revealed

Following beginning of production the B heavy-duty war trucks and completion of designs of the A and AA sizes, the Military Truck Production Board started on its work for the maintenance of the trucks in France. George C. Randles, in charge of the manufacturing equipment, together with James F. Borquin, head of the production work, made a thorough investigation of truck repair on the Mexican border, learning the achievements and the errors of the past. They found some shops excellent, others not so good, with the chief problem that of the inefficient soldier mechanic, soldier foreman and soldier superintendent, who were found among the many soldier mechanics, foremen and superintendents at work.

Many repair jobs were found to be wrongly handled because of ignorance, others because of different opinions between mechanics, and still others because of inferior machinery and tools. The result was the decision to standardize insofar as possible.

The repair base units have been planned on standardized lines. Each average building will have 230,000 sq. ft. of floor space. All buildings will be exactly alike with stock rooms, tool rooms and racks the same in each. And the general plans for these buildings are so arranged that in event the building should be made larger or smaller the change in the plans can be made within a very few minutes by adding or taking away the number of bays required, without affecting the efficiency of the plant. These plans also include consideration of light, heat, power, etc., which can be increased or decreased at will along similar lines.

The value of this plan lies in the fact that where workers are taken from one plant to another they can at once enter upon their duties without strangeness, knowing where to find stock, accustomed to the tool racks, used to certain methods which can be pursued equally well in the new shop. For example, the Quartermaster Corps is now building a large mechanical repair shop unit at Baltimore, where 2000 mechanics will work on the trucks coming overland from the factories to the seaboard. Construction of this plant and also of the warehouse which will adjoin it and serve as a commissary to the trucks began last week. Completion is expected in 90 days. If after these mechanics have been thoroughly trained at the truck repair work in this shop the War Department decides to send them to France, it will be a simple matter. The men can be transferred readily, and when they enter the shop in France will find the stock rooms, tools, machinery, light, power laboratories, everything exactly as in Baltimore.

Manual to Guide Mechanics

The next standardizing step is that of rebuilding and repairing. There are certain fundamental principles of mechanics for this work, and the plan provides a system that insures that each mechanic will follow the proper methods. A book to be known as the Shop Manual is now being compiled which so definitely lays down the rules to be followed for repairs that it will be impossible for a mechanic or a foreman to use his own judgment. The plan insures uniform work at every base and on every job. Instead of depending upon the foreman to say, for example, that a cylinder is not in need of regrinding, the workers will turn to their manual, which strictly defines the cylinders that are out of round or tapered beyond good practice and definitely specifies the regrinding and the oversize, which is also standardized. This also applies to the crankshaft, where if the pins are egg shaped all must be ground to a certain undersize to clean up properly. In this way every job must be done thoroughly.

Digitized by Google

and there will be no opportunity for men to use individual judgment or to experiment at a time when experiment may mean a penalty of lives. The shop manual is now being compiled and will be completed in the near future.

All tools and machines are being standardized in so far as this is consistently possible with good judgment. All machine tools, for example, are standard belt driven because belt-driven machine tools are easier to secure than motor driven, because there is always possible the conflict of alternating and direct currents and of different voltages in the use of the motor driven, and because with a line-shaft drive if emergency demanded a gasoline engine could be attached and used efficiently.

All mechanics' tool kits will be standardized, each mechanic of the different classes carrying identical tools, which will be subjected once a week to military inspection, much the same as with the arms of the infantry soldier. This inspection will apply particularly to the finer tools, which have to be almost perfect to insure efficient results.

Thus between the standardized shops, machines, tools and repair instructions of the shop manual, every truck entering the shop for repair will proceed through exactly the same movements from entrance to exit that every other truck in its class will pass.

The standardization extends also to the mobile repair units, the trucks carrying small repair shops aboard for making field repairs. These will carry standardized repair tools and machinery, and plans are now being made to perfect every detail of the repair mechanism to the highest degree. For example, a large drilling machine in the original equipment has been eliminated and a small drilling attachment substituted that is more efficient, and the original lathes standing on two legs, which were unable to withstand the shocks over the roads and usually resulted in lathes out of line, have been changed so they rest on a center pedestal over a cabinet, insuring firmness of position.

The numerous results of this system are quickly apparent. They include:

The making of good mechanics, versed in the fundamentals of efficient repair work.

The elimination of the "hammer and cold chisel" sort of repair men, well known to the average motorist.

The training of men mechanically and with a discipline that will make them most valuable in civil life.

The elimination of all chance for experiments. Familiarity with shops and systems instead of strangeness with every transfer.

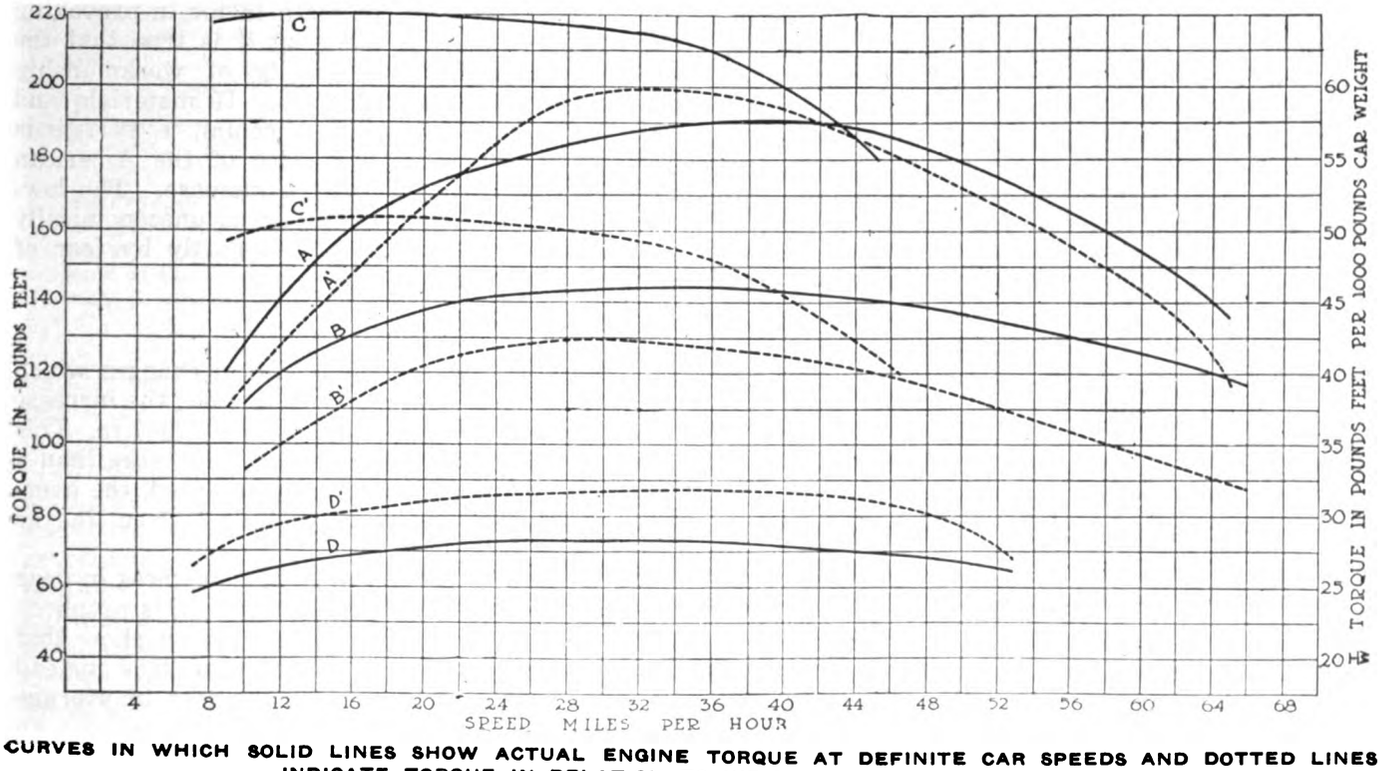
A repair system that insures maximum efficiency in the maintenance of the quartermaster trucks in France.

The average base repair unit is expected to hold 1163 men under the direction of a major.

The plan of organization of this general scheme of maintenance includes:

Supervision of standardization by George E. Nandles, whose duties include provision for standardizing all buildings, power plants, stock rooms, warehouses, lighting, heating, plant transportation, manufacturing equipment and methods, together with various details connected with modern plants and manufacturing practices for the work to be performed and the compiling of all data necessary. He is being assisted by:

F. A. Barnes, industrial engineer of Cleveland, Ohio, whose duties include building design, building construction, cranes, power plants, water, heating, lighting and sewage.



D. C. Selheimer, production engineer, formerly with the Packard Motor Car Co. and the Hal Motor Car Co., who is working out the details of all manufacturing equipment, such as machine tools, small tools, mechanics' tools, shop transportation, arrangement of departments and manufacturing layout details. He will be assisted by Lieutenant Rogers.

Major North, who will provide complete plans and specifications for recommendations for procurement of various items; follow up purchases and maintain purchasing records.

Lieutenant Lord, who will work out the shop manual of standardized operations, together with parts lists and instruction books of the Class AA, A and B trucks.

B. H. Eaton, who is arranging details of plant systems, including tool cribs, warehouses, receiving, stock room and shipping.

Major Parramore, an army officer, who will act in a consulting capacity. Major Parramore has seen active truck repair service on the Mexican border.

CURVES IN WHICH SOLID LINES SHOW ACTUAL ENGINE TORQUE AT DEFINITE CAR SPEEDS AND DOTTED LINES INDICATE TORQUE IN RELATION TO WEIGHT AT THE SAME SPEEDS

A=Six-cylinder, 3½ x 5, geared 4.46 to 1, 35-in. wheels; weight, 3214 lb.
B=Eight-cylinder, 2⅞x4¾, geared 4.05 to 1, 34-in. wheels; weight, 3375 lb.
C=Twelve-cylinder, 3x5, geared 4.36 to 1, 35-in. wheels; weight, 4375 lb.
D=Four-cylinder, 3x4¼, geared 4.70 to 1, 30-in. wheels; weight, 2200 lb.

A'=Car A plotted against T/W per m.p.h.

¶ Engine Revolutions Per Mile Are Lowered and Tire Sizes Slightly Increased—Expected Weight Reduction Has Not Materialized.

By A. Ludlow Clayden

ON another page in this issue is a chart which shows the rapid rise into favor of the spiral bevel—how it arose in January, 1915, shot upward, became the standard type almost. The curve starts gently, rushes up rapidly and then tails off gradually.

With a different notation the selfsame curve might very well be used to represent engineering activity in the passenger automobile field for the same period.

The year 1917 has been one of practically no development. War has stopped experiment in many directions, and the realization of war has not been with us long enough to have started it in other lines. The immediate effect of war is a large increase in average price, but this is purely temporary. It does, however, serve to drive home the fact that the sort of cars building to-day are rendered more costly by difficult conditions; and in similar measure the cost of operation has been raised in common with nearly all other living costs. The automobile engineer's next task is to fight and conquer cost of operation—to produce cars which will do essentially the same work for the old price instead of the new one.

None the less the trends shown in the analysis of all the chassis listed in January, 1918, will in the future come to be one of the most interesting series ever prepared. The present year must be a turning point in many ways; it cannot fail to mark a point of change in automobiles as in so many other things.

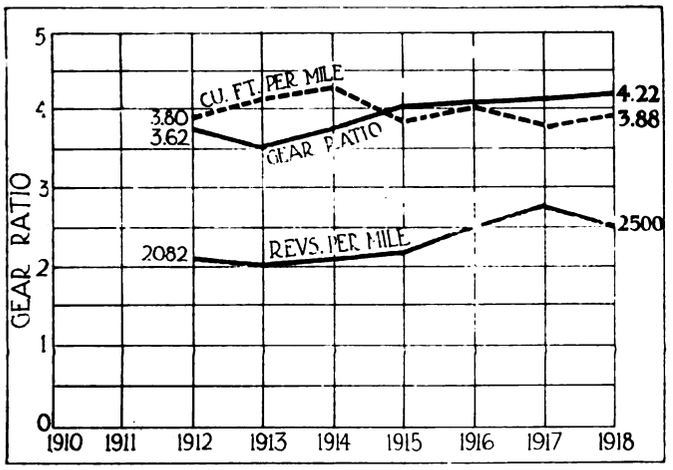
Meaning of Average

Before proceeding to analyze the trends it is necessary to make the annual explanation of the fact that by considering all the chassis listed without regard to the output of each maker the averages deduced are averages of engineering opinion; and it is this which such analyses seek to discover. An analysis by production would throw into absurd prominence the features of a very few cars which happen to be very cheap and to be made in huge amounts. That which the small producer is doing to-day the big producer will generally be found to be doing to-morrow.

Average Price $1,822

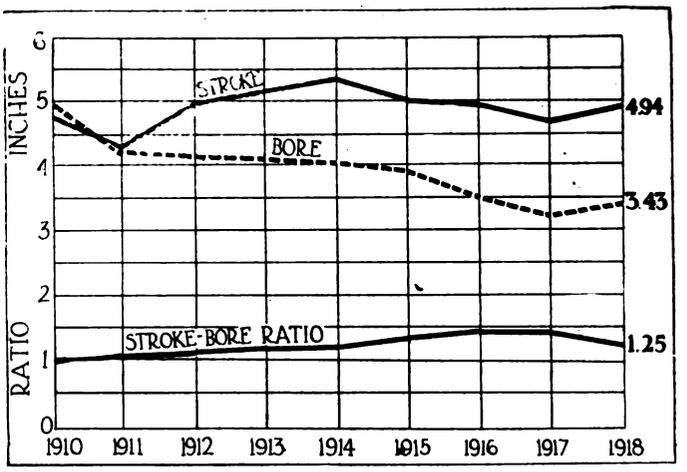
From $1,687 to $1,822 the average price of the American made five-passenger touring car has risen a total of $135 in 1917. The bottom price was touched two years ago, when the average was $1,600. The present price is $96 less than the average of 3 years ago. Of course it is the rising cost of everything which has been the main factor in provoking the rise in price this year, but it is true that the tendency toward better quality of workmanship noted last year has continued. If materials and labor had not risen in price since Jan. 1, 1917, it is probable that the average price of the American car would still have shown an increase. The low-water mark of January, 1916, was uneconomically low; it was a low price caused partly by fear of decreasing demand.

Wheelbases Are Longer



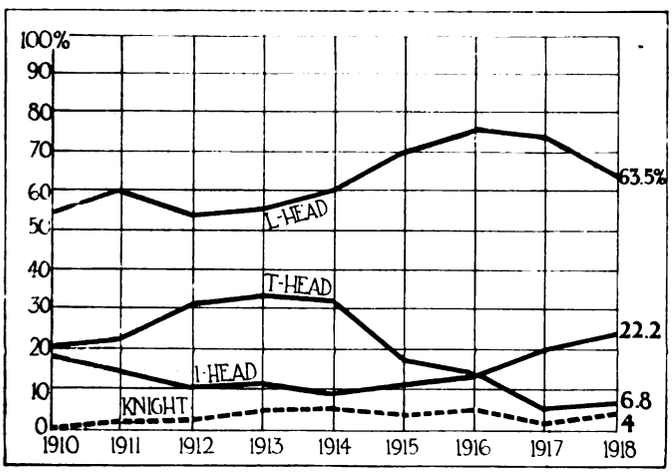
There have been some mechanical changes which stand out prominently, as, for example, the increase in average wheelbase from 113¼ to 120¾ in. This takes us back to the average of a little more than a year ago. Engine size has also enlarged, the average piston displacement now being 269 cu. in., as against 222 last year.

It was commented last year that lowness in gear ratio had probably been reached, and this prophecy is upheld by the present figures, which show that the revolutions per mile now average 2500 instead of 2726. This is owing to an increase in average tire size from 31 to 34 in., for there has been an actual decrease in gearing ratio, last year's average being 4.15 to 1 and this year's 4.22.

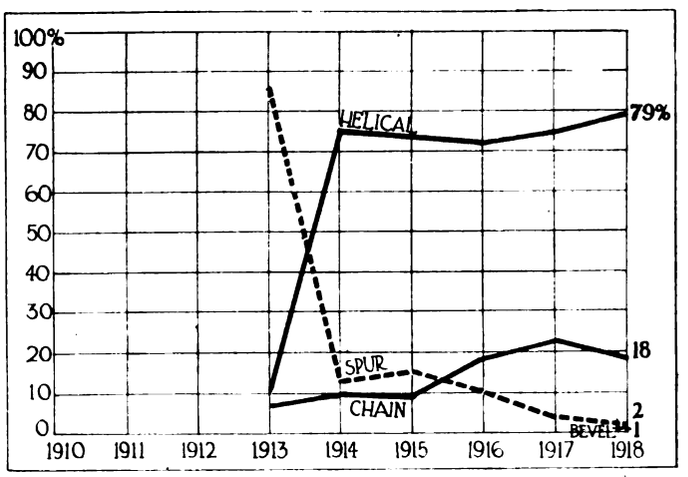


Among all the other averages tabulated there are few showing more than the very slightest alteration. Most of the curves illustrated follow their

Digitized by Google



1918 Automobile Engineering Tendencies



Compared with last year the crankshaft revolutions per mile are 2500, whereas a year ago they were 2726. Average tire sizes have increased and the rear axle gear ratio which one year ago averaged 4.15 to 1 to-day averages 4.22 to 1. The reduction in car weight anticipated a year ago has not materialized largely due to war conditions greatly restricting engineering changes

This year, 1918, models show an increase in engine size, the average piston displacement being 269 cu. in. instead of 222. For three years previous to 1918, the engine displacement has been constantly growing less until the upward tendency of this year. The bore and stroke ratio has dropped from 1.36 last year to 1.25 at present; the average cylinder size to-day is 3½ by 5 in.

The increase of the valve-in-the-head engine which has been gaining steadily since 1914 continues, the net gain this year being 2.2 per cent, which is made at the expense of the L-head, which for 2 years has been losing in the percentage list. The T-head has held its own and the Knight type has gained

In the drive of motor accessories, three positive trends which gave indications one year ago are continued. Helical drive after its phenomenal use of 5 years ago continues to gain, whereas chain and spur gear drives continue the downward curve which was in evidence last year

natural tendency; as, for example, the rise in the percentage of overhead valve engines, and the increase in popularity of the disk clutch.

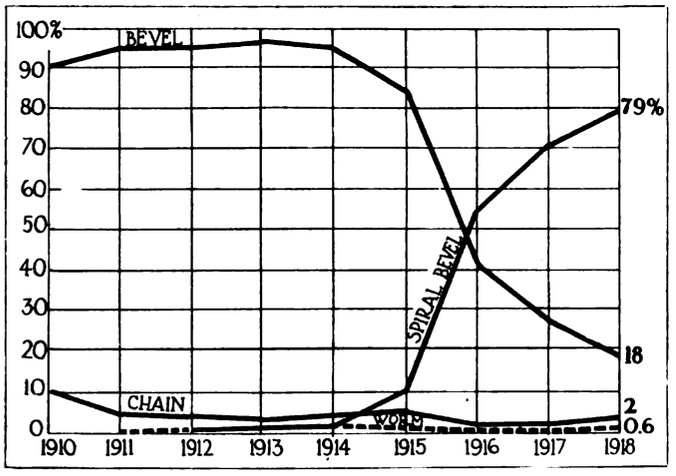
Cylindricity remains much the same, rather more sixes; 51.7 as against 47 per cent and fewer eights and twelves in proportion. There are six fewer makers and twelve fewer chassis listed in the specifications.

Nineteen seventeen has been a year of manufacture rather than of design. It has been a year when a manufacturer's task was to get material and not to improve his machine—a year when engineers have been handicapped as never before. The only changes which really count for anything, which are matters of principle as distinct from body changes or other matters of fashion, are those made to facilitate the burning of heavier fuel. These changes probably mark the beginning of a new era. They probably are the heralds of the time when gasoline will cease to be the motive power of road vehicles. The change is from the purely gas engine to something more allied to the purely oil engine. Instead of merely metering the fuel and mixing it with air, the later engines vaporize the fuel as well, or partially vaporize it. We are within sight of the practical engine which will *start*, as well as *run*, on fuel with no light fraction if necessary; of the time when double the present percentage of crude will be available as an automobile fuel.

Many of the anticipations of a year ago have not been realized, largely owing to the impossibility of doing much development work. Thus the expected general decrease in weight has not come about. Aluminum remains too scarce and expensive and

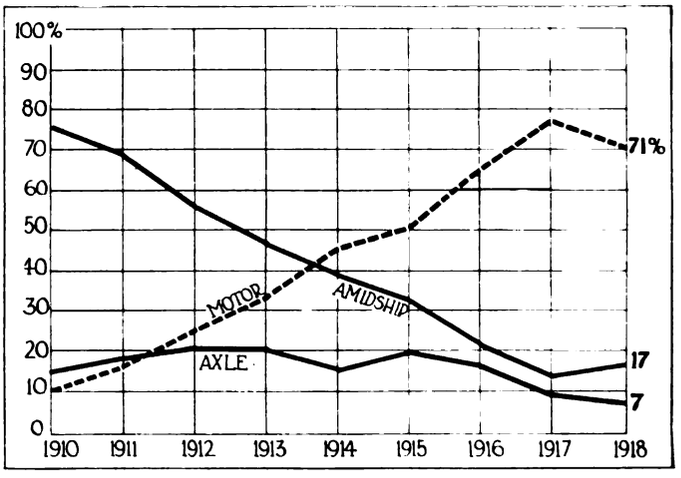
Digitized by Google

the high-grade steels required are in the same category. Electric or magnetic drive is another feature much discussed in 1916 and now hung up by war conditions.



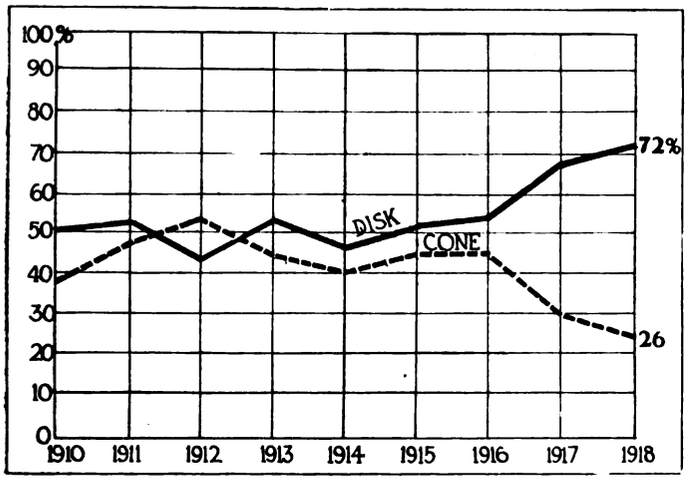
The year of greatest change was 1915. Nineteen sixteen was the year of greatest production; 1917 has been a year of consolidation of the engineering development of 1915 and the engineering experience of 1916. A great many old-fashioned stock parts have vanished. There has been a considerable cleaning up of stock motors in particular. The period of spring experimentation has ended in a triumph for the semi-elliptic, although the cantilever and platform and even the elliptic springs have still their supporters. Argument that any one form has inherent advantages over another has ceased, it being realized that it is possible to get any desired result with any type of spring if sufficient care is taken with the design.

In axles, steering, electrical gear, carbureters and transmissions there have been no changes worth mentioning.

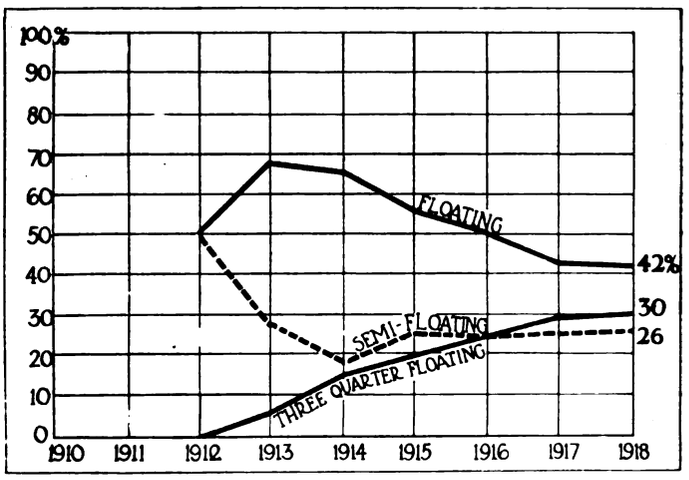


The alleged shortage of materials has failed to materialize in a drop in the use of alloyed steel for chassis parts. The percentage of alloyed steel in the chassis is relatively small, and even though there are detailed alterations in parts to permit of the use of the high-carbon product in some instances, these alterations have not been of enough importance to show up in the tabulations and curves.

Trends in accessory design have not been marked. Perhaps one of the features of the year is the introduction of improved priming devices to aid in overcoming starting difficulties. Accessories which are used as standard fittings such as steering wheels, dash meters and gages have not been materially altered, although their arrangement is such that the devices are more easily seen by the driver.



Engineering Trends Shown by Curves



The trend of rear axle design started in 1914 has continued consistently to date, with spiral bevel rising steadily to 70 per cent, bevel losing steadily and now at 18 per cent and worm and chain remaining stationary. The popularity of the spiral bevel is marked

It was in 1914 and 1915 that definite trends in gearset location set in, although the last year has introduced some counter movements, notably the falling off of mounting as a unit with the engine, and a corresponding gain of the amidship location

From 1910 to 1916 the clutch field was quite evenly shared beteween the disk and cone, with the cone leading in 1912, but since 1916 the disk has gained so as to have nearly three times the percentage following the cone has

The definite movement in rear axle design extending over 8 years has been the constant, consistent gain of the three-quarter floating type and the equally steady loss of the floating design; the semi-floating type has held its own

Digitized by Google

Engine Design for 1918

Cylinder Sizes Slightly Larger Than 1917 — Pressure Lubrication Has Gained — Overhead-Valve Types Increasing — More Counterweighted Crankshafts — Bore-Stroke Ratio Is Lower—3½x5 Average Size

PROBLEMS of heavy gasoline have completely ended the cylinder controversy. Looking backward over the past three years it seems that the eight and twelve have served to bring back the four into higher favor, since despite a decrease in the proportion of fours in the whole list there have been several new high-grade fours put on the market in the last two years. It was predicted by Howard E. Coffin that the eight and twelve would compel the production of *better* sixes; and this has indeed come to pass, for the average engineering quality of the stock six-cylinder engine is far above what it was even a year back.

The Average Cylinder

The nearest to an average for all American passenger cars would be a six-cylinder machine with an engine having dimensions 3½-in. bore by 5-in. stroke. The engine size proportions and variations in dimension with the different numbers of cylinders are rather interesting. Of all the cars listed in the specification tables, eliminating chassis which are duplicates except for wheelbase variation, 34.6 per cent are fours, 51.7 sixes, 10.2 eights and 3.4 twelves. The grand average dimensions are 3.93 by 4.94 in., giving a displacement of 269 cu. in. Splitting the engines up in order of cylinder number gives the results following:

Cyl. Number	Bore	Stroke	P.D.
4	3.6	4.95	221
6	3.46	5.00	282
8	3.13	4.59	282
12	2.87	4.96	386

It is a curious thing that the average size of the six and eight should be the same, and probably this may be taken as meaning that the normal, medium-size car of to-day is best suited by an engine of this size. It is perhaps a little surprising that the fours average so high a displacement. Allowing for the fact that many of the fours have small wheels, this probably indicates that the displacement per mile run differs only a little as between the sixes, eights and fours.

The average engine is larger than it was a year ago; 269 cu. in. as compared with 222; the gear ratio has changed from 4.15 to 4.22, yet the increase in average tire size from 31 to 34 in. has prevented a large increase in the displacement per mile run on high gear. A year ago this averaged 384 cu. ft., and it now comes out 388 cu. ft. This means that ability as measured by displacement per unit of distance has not been increased. Probably there has been a little increase in mean effective pressure, especially among the newer sixes, but this will not have been great. On the whole, therefore, the ability ratio may be said to be unchanged.

There are more overhead valve engines by 2.2 per cent, and fewer L-head motors. Also there is a new type never before listed on stock cars, this being the horizontal valve. This is employed on the new Duesenberg stock engines, and this motor is used on 2.3 per cent of the listed chassis. The listed Knight engine chassis have doubled in proportion, increasing from 2 to 4 per cent.

Thus while the L-head motor remains the commonest type, it is apparently on the wane. Taking the years 1915, 1916 and 1917, the L-head showed 70, 73.3 and 73 per cent, while it has now dropped to 63.5 per cent, and a falling off of 10 per cent in a year of stagnation in design is significant.

There are no more adherents to the multi-valve idea sponsored by Stutz and White, but this is perhaps due to the paucity of new designs. It is a somewhat expensive design and most novelties are in the direction of cheapness rather than increased cost.

Unfortunately figures for the proportion of detachable cylinder heads are not available, since there has without question been a large increase in its use. It is a long time since any new engine has appeared without this feature, and this year has seen Cadillac change over as well as Packard.

Single Ignition Leads

Ignition has followed the natural trend toward single-current source, this being now the battery. Details have been improved in both batteries and breaker mechanisms, so the magneto shows no signs whatever of returning to its original position of universality despite its continued employment on many of the most expensive cars. The weakest points in ignition systems are now the automatic advance, which is developing slowly but surely, and the material available for contact points. Both platinum and tungsten are so scarce and so much in demand for war purposes that every magneto and distributor maker has had his troubles in maintaining the supply of contact material. The established manufacturers have been able to keep up the quality fairly well, but with the return of peace a

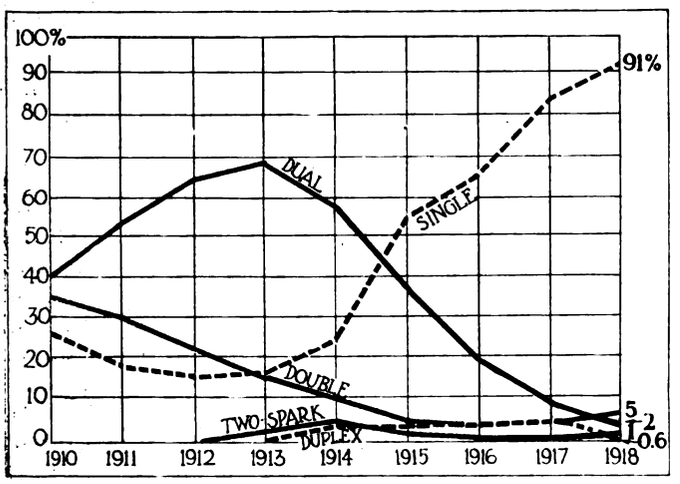
Digitized by Google

big increase in the life of contacts will be observed.

Engine balancing has been a continued study during 1917, and the day of the counterweighted crankshaft has arrived. There is a considerable difference of opinion as to how far it is really necessary to go in balancing, this subject being as yet only partly understood. The matter is discussed fully in another part of this issue. Still the 1918 Show does mark the emergence of the counterweighted crankshaft from the peculiarity stage into the realm of conventionality.

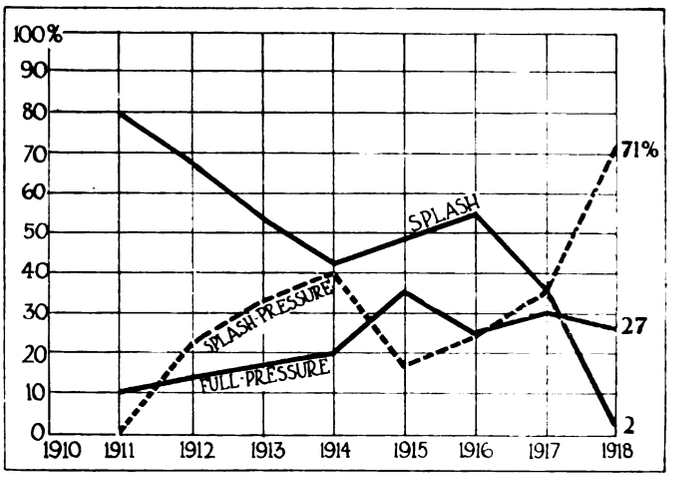
Pressure Oiling Gains

In lubrication, circulating splash or combined splash and pressure systems have gained a great deal. In percentage the full pressure system has fallen off a trifle from 30 to 28 per cent, but this is due to decrease in models rather than to decrease in the number of believers in the system. In the tabulation the old style of separating splash-pressure and circulating splash (trough system) has been abandoned because of the many degrees of variation possible. Some engines have practically a full-pressure system plus dip troughs for the connecting-rods, and some rely mainly on the troughs but use separate feeds to the main bearings. The real distinction comes now between those engines which have the troughs as an accessory or as the main lubrication source and those which rely entirely on pressure and have no dip for the connecting-rods. Thus the two percentages given under "splash" and "splash-pressure" last year should be added together in comparing them with the total of 71.6 per cent for this year, and we then see an increase for this system of 1.6 per cent. There is only one car listed with plain splash lubrication, that is dip for the connecting-rods without troughs.



In pressure systems there are many variations. Last year it was anticipated that the 1918 tabulations would show a strong trend toward controls which would proportion the oil supply to the engine bearing loads. This has not come to pass. Most of the pressure systems are low-pressure systems; that is to say the maximum shown in the gage with warm oil seldom exceeds 10 lb. per square inch.

Probably the difference between splash-pressure systems and pure pressure ones has been exaggerated. The former is only different in that oil is supplied to the crankpins externally instead of internally. The pressure shown on the gage in a full-pressure system is often higher than that prevailing actually between the crankpin and its connecting-rod bush; while oil supplied externally to a connecting-rod is given some pressure by the relative reactions within the bearings.



Speaking broadly, the majority of manufacturers whose prices permit the drilling of the crankshaft prefer to supply the pins in this way, and most of those who prefer to use dip troughs do so because they give almost the same if not quite the same results when in combination with direct feeds to the main bearings. The leading advantage of the pressure system is that it gets the oil to the bearing surfaces quicker in cold weather, and most of the wear on bearings takes place during the first five minutes of running.

Probably the most satisfactory feature of engine improvement is in the line of better volumetric efficiency. Engines are giving bettre torque curves and higher ultimate performance, simply because they are being filled better on the intake stroke. This is true in spite of the fact that the intake passages are heated to a higher temperature now than ever before, thus, although there is a normal expansion of the gases due to the higher temperature of the intake, this expansion is more than compensated for by improvements in cam design and by carbureter manipulation resulting in higher velocities of the intake gases.

The so-called hot spot intake does not do anything towards making engines easier to start. It has a marked influence, however, in shortening the period of warming up, and this is highly gratifying to the user of present day fuel.

Ignition movements since 1914 have been generally consistent. Thus single ignition that started gaining in 1912 has risen constantly and is now a 91 per cent factor and dual and double has been consistently losing. The two-speed movement is stationary

Last year the engine lubrication field was almost equally divided, with 35 per cent each for splash and splash pressure and 30 per cent for pressure. In the last 12 months splash pressure has doubled its following and the other two divisions have lost, splash being almost eliminated

1918 Chassis Design Features

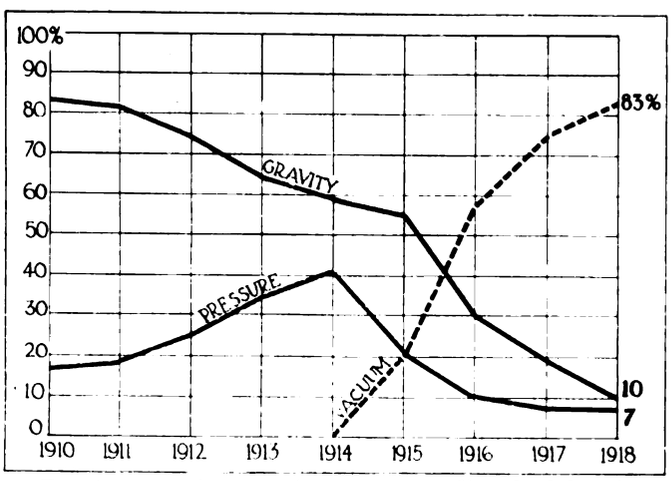
Semi-Elliptic Springs Established—Wheelbase Raised from 113 to 120.7 Inches—Frame Changes—No Weight Reduction

APART from changes in engine design extremely little has been done this past year. Chassis were greatly cleaned up in 1915 and 1916; there is not room for a great deal more change without introducing new principles. The gearsets produced by the stock-parts makers are nearly all identical with previous designs, the axles are likewise unaltered and there are no novelties in steering gears worth mentioning. Even spring design has been stagnant.

The three-speed transmission integral with the engine as a unit is found on three-quarters of the listed cars; the relative proportions of full and semi-floating axles remain about the same; there is nothing new in frames or springs. The spiral bevel is the predominant form of final drive, having increased from 70 to 79.4 per cent. Wheels are larger, being now shod on the average with 34 by 4-in. tires instead of 31 by 4-in., a return to the conditions of January, 1915, which is a little surprising in the light of the popularity of the 32 by 4-in. tire. There are more wire wheels, these being now either standard or optional without extra charge on 27.8 per cent, leaving 72.2 per cent on which only wood wheels are fitted. This is mainly a manufacturing matter, and if progress is normal during 1918 there will be more wire wheels to list in January of next year.

Semi-Elliptic Most Popular

In springs 44.4 per cent of the listed chassis have semi-elliptic, 29.6 cantilever and 17 per cent three-quarter, the balance being divided between platform, transverse and special systems. Two cars, the Jackson and the Franklin, remain the only users of the elliptic system. Cadillac, Dorris and Peerless are the only cars using platform springs, Packard having changed to semi-elliptic. Hotchkiss drive is used on 53 per cent of American chassis to-day.



Increase in wheelbase to an average of 120.7 is unexpected, since last year it had shrunk to 113. The present figure is almost the same as that prevailing the year before last. It means that the average body on 1918 cars will have perceptibly more leg room. Of course a slight increase in wheelbase is to be expected at a time when we also see an increase in six-cylinder models, but a couple of extra cylinders on 5 per cent of American chassis is not enough to provoke more than a fraction of an inch on wheelbase average.

A change which does not show on tabulations, but which is quite important is that toward deeper frame sections and stiffer frame construction. This goes hand in hand with the tendency to use more leaves in springs, in that its sole purpose is to make for better riding. It is hardly possible to use an 8-in. frame section except when entirely redesigning a chassis, so in this quiet year there have been few extreme cases of deep frames. A good many manufacturers have added a half-inch, or some similar amount which is insufficient to necessitate completely new brackets all over, a new motor support, and so on. Still it is certain that the next redesigning period, which will most probably be the year after peace is declared, will see automobile frame construction greatly changed. Such frames as the Marmon and the Premier are typical of the construction of the future.

Weight Reduction Halted

Weight-saving in chassis parts which had begun a year ago is halted by the present need for using only medium-grade materials wherever possible. The amount of interest which the automobile engineers are now taking in aviation will certainly provide them with plenty of ideas for the future, and many have plans laid for a much lighter after-the-war car.

Every year for many years, in reviewing the annual progress of either America or Europe, it has been necessary to remark that steering and brake design are on the average poor. The *best* in brakes and steering is much higher above the *average* than is the best of most other features. Steering gear and the brakes remain the poorest parts. Nothing has been done in 1917 which can be regarded as a general improvement. It is a welcome feature, however, that accessibility in the front compartment has been noticeably improved because of the almost universal increase in leg room. This has been as much as 2 in. on a number of cars.

For 4 years the use of vacuum gasoline feed has increased steadily, and gravity and pressure feed have decreased just as steadily. Present curves would indicate a further continuance of these movements

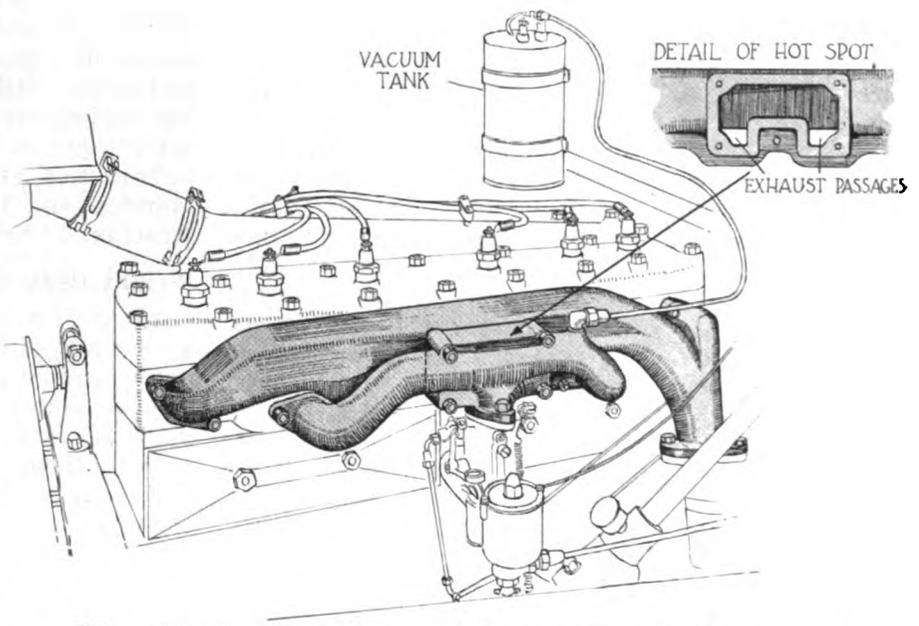
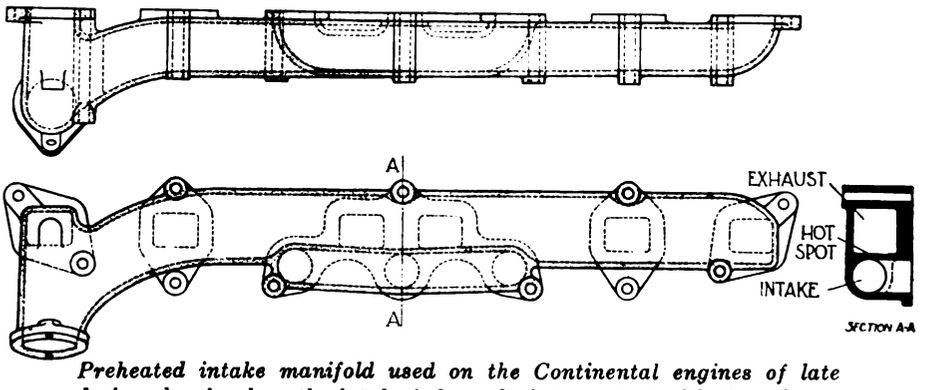
Modern Manifolds

Hot Spot, First Effect of Scientific Study, Still Semi-Experimental — Too Much Heat Injurious—Four Typical Examples



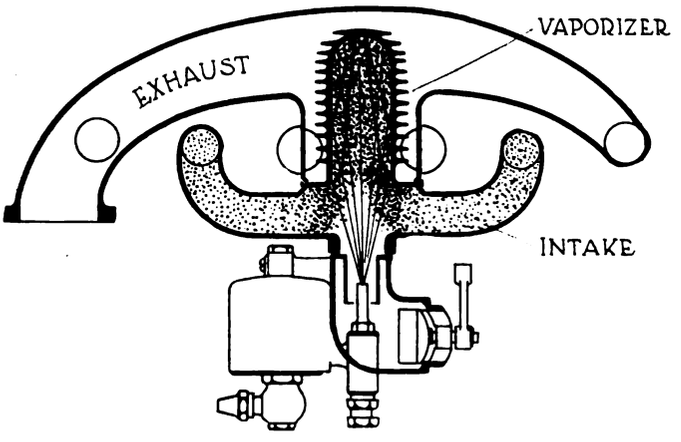
ONE of the details which have been given the closest attention during the past year has been the intake manifold and the methods used for preheating it. It has been universally conceded that owing to the high boiling point of the present-day fuel it is necessary to apply external heat before proper care can be taken of the fuel. The methods, however, which have been utilized to secure this heat differ in a great many respects.

Owing to the fact that flexibility is one of the main factors demanded of the passenger car, care has to be used in how the heat is applied. It is readily possible to secure an excellent mixture for *constant* throttle conditions, but when the varying throttle conditions met with in passenger car practice are taken into consideration, it is not so simple to secure the flexibility. Preheating the fuel and preheating the intake air before it comes in contact with the fuel are both methods which work out satisfactorily for constant throttle openings. For variable throttle openings, however, it is necessary to heat the intake mixture and also to preheat the air in addition, to some extent, depending upon outside temperature conditions.



It must be conceded that the hot-spot intake manifold does not completely solve the heavy-fuel problem. There are weak points in its application, although it cannot be denied that it has many good points and it does do the work well, if not at all times in a perfectly satisfactory manner. Where it falls down is in starting.

Another place where it is weak is that when running slowly there is a lack of heat, and when doing heavy work, such as on hills or on sandy roads, there is an excessive heat. It is the starting problem which presents the most serious difficulty at the present time. It is because of the cold starting condition that so much of the fuel works its way past the piston rings and into the crankcase, giving rise to crankcase dilution, where the lubricating oil is so reduced in quality that it becomes a menace instead of a benefit to the engine.



This matter of cold starting is the

Hot spot used on the ram's-horn intake manifold on the latest type of Chalmers engines

A typical hot spot arrangement—section through California heavy fuel vaporizer for Fords

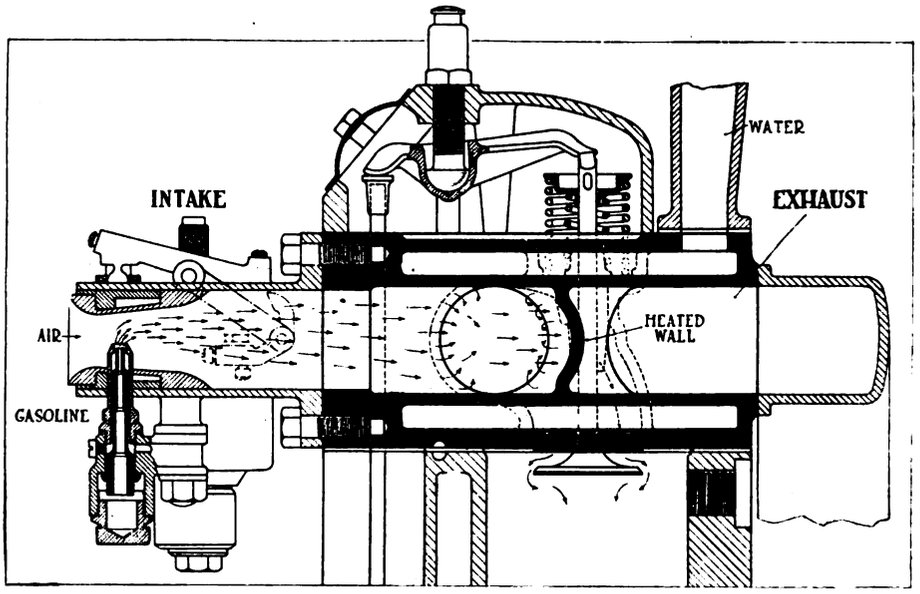
Digitized by Google

Digitized by Google

Digitized by Google

next thing which must have the attention of the designer, and it is surely going to mean that some extra equipment must be added to the car to take care of it as it should be handled.

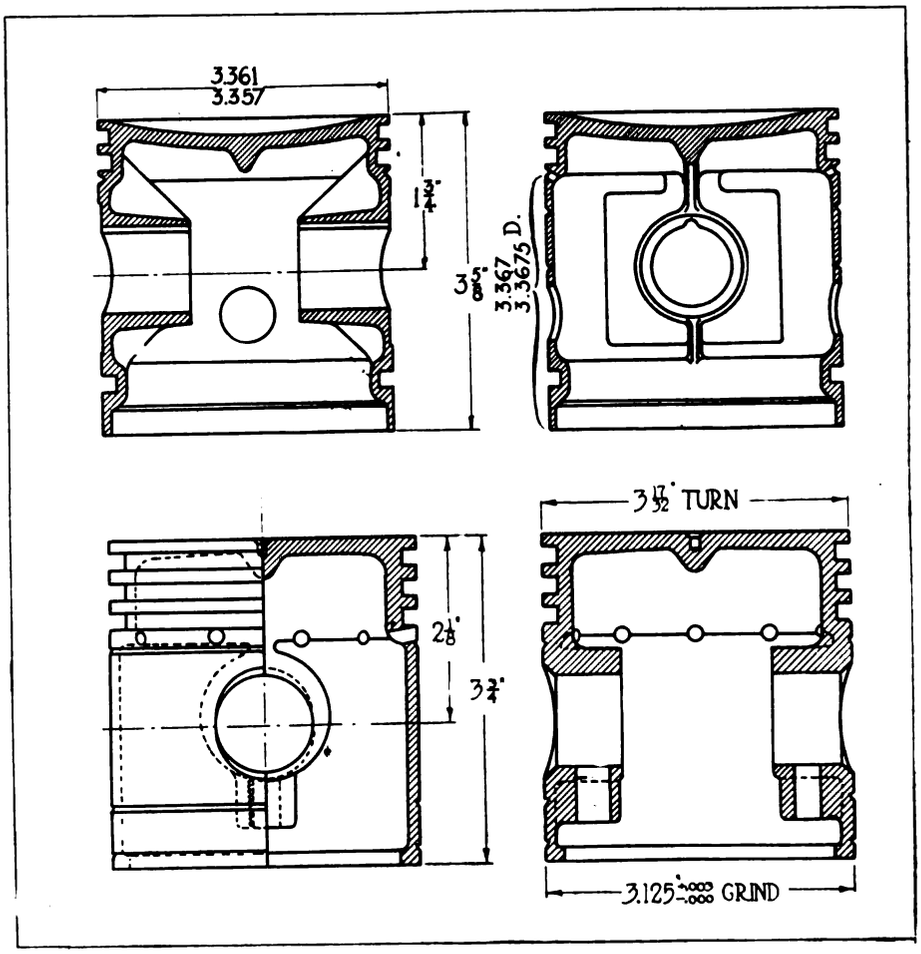
One company is placing a heat coil in the carbureter float bowl, and other companies are experimenting with the use of a heated coil at other points of the intake system. This may be a solution to the cold starting problem. If it is not, it is at any rate a long step in the right direction.



Once the engine is running, there is no doubt but what under normal conditions the hot spot provides the final step necessary in completing vaporization of the fuel. The unvaporized globules of non-volatile fuels which impinge against the hot spot are immediately transformed into vapor and the loss of volumetric efficiency is not great; in fact, a study of the torque curves of the engines using hot spots shows that there is an improvement in torque in a great many instances, due to the use of the hot intake.

The opinion that the hot-spot intake is the best way of handling the situation is not unanimous. Some engineers raise the question as to whether it would not be better to have a much larger water jacket on the carbureter and intake manifold in handling the present-day gasoline. It is claimed that the water heats up more readily, it keeps hot during short stops, and never heats the mixture to excess. Furthermore, it is claimed that it is easily regulated for summer and winter running, and it appears to give very satisfactory results. Of course it will not give sufficient heat to satisfactorily use kerosene.

Air Must Be Preheated



Even with the integral intake and exhaust, where the intake is exposed for some distance of its length to the direct heat of the exhaust manifold, it is necessary to preheat the air to some extent. The amount that the air is preheated, however, should be varied for summer and winter conditions. The system used on the Model R Hupmobile may be cited as an example of where the principle is applied, as there is a summer and a winter position for controlling the pre-heating of the intake air.

Another system which may be cited as typical is that employed on the Hudson carbureter, where, in the latest model, no hot air horn or stove is used at all. Owing to the employment of the shutter on the radiator, the space beneath the bonnet becomes practically a closed room, and it is heated in accordance with the necessity of the case, depending upon the temperature of the external air. The colder it is outside the more the shutters are closed, and, conversely, the warmer it is the more the shutters are open.

Section through Brush manifold showing how gasified fuel enters intake gallery while liquid particles strike heated wall where they are evaporated

Summing up the matter of hot spots, it appears that they offer as good a means as we have available at the present time for handling a difficult fuel situation. Under average running conditions it provides a good, clean, dry mixture without sacrifice of a material amount of volumetric efficiency. Its weak points are the conditions of starting and the unusual conditions of very slow running in cold weather and pulling through heavy roads in hot weather.

Variety in Auxiliary Drives

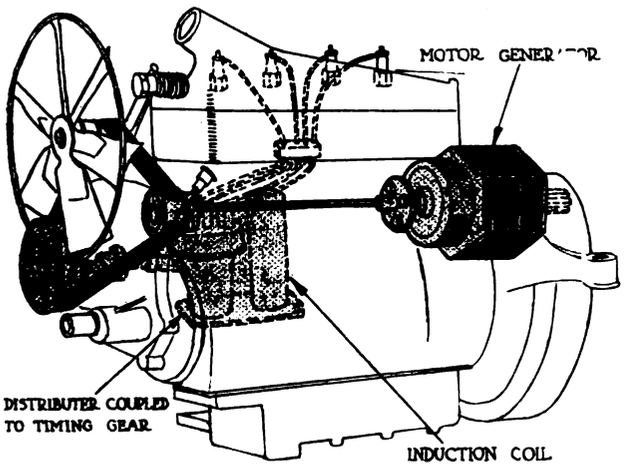
Disposal of Engine Accessories Far from Standardized—Different Schemes Have Individual Advantages—Trend Keeps Units High Placed

THE layout of the auxiliary drives of an automobile engine is of supreme importance in securing the proper performance of these parts. In a great many instances the satisfactory performance of a unit depends entirely on the method of attaching it to the engine and to the method of drive, as well as to location. There are a few fundamental facts which are well realized and which are closely adhered to in up-to-date practice. Probably the first consideration is that the drives be as compact as possible, and wherever it is at all feasible one drive should take care of two or three units. This has been growing practice and is a noticeable element in securing lightness of the powerplant. The combinations which have been worked out show a great amount of ingenuity in this respect.

For example, Oldsmobile and Nash might be cited as typical, in that the belt which operates the fan also operates the generator. On the Oldsmobile this drive passes on to the distributor, while in the Nash a separate distributor drive is used in the center of the engine, operated from the camshaft.

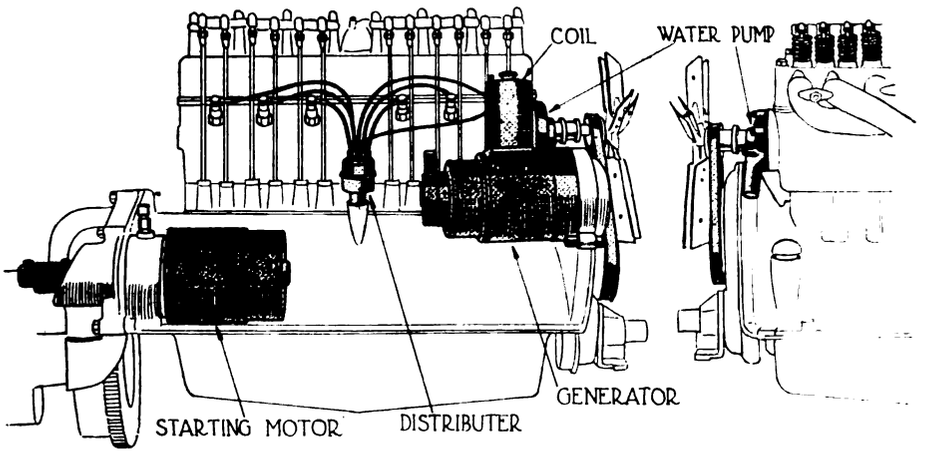
This practice of combining drives is one which could be carried out much further than it is. Where individual drives are taken for each of the auxiliary parts, a much greater amount of power than necessary is consumed, and there is sure to be a tendency toward noise, because there are so many more parts in which quietness must be maintained.

Short Plug Leads



Another feature which is of considerable importance is that the distributor be placed in close proximity to the spark plugs. The amount of current which can leak from the spark plug leads is remarkable, and with the high tension current a small leakage will materially cut down the heat of the spark and reduce the speed of ignition, lowering the rate of flame propagation, and thus reducing the mean effective pressure.

With this in mind it has been practice on the part of some designers to extend the distributor shaft so as to bring the distributor close to the spark plugs. The Hupmobile is a good example, the vertical shaft being extended upwards to bring the distributor above the top of the engine, thus giving comparatively short leads. It is also necessary for the same reason that the coil be located quite close to the distributor, as leakage between the coil and the distributor is just as harmful as it is between the distributor and the plugs.



The tendency towards separating the starting motor and the generator is growing, but it is by no means universal. A very compact unit is used on the Dodge car, and a balanced drive is secured by placing the starter-generator on one side of the engine, with the water pump and distributor on the other. As shown in the sketch herewith, the distributor mounting on the Dodge is solid and at the same time affords a support for the coil.

Balance the Drive

Where more than one drive is necessary, general practice appears to be in favor of establishing balance as far as possible by putting the units to be driven on opposite sides of the engine. This balancing scheme can be car-

ried out quite completely in V-shaped engines where the duplicated members can be balanced on opposite sides of the crankshaft, while the single members can be put on the center line of the engine. The example shown herewith of the Cadillac illustrates this very clearly. The two water pumps are on opposite sides of the engine, with the distributor and the motor generator mounted on the center line between the V.

Starting motor supports are better this year than they have ever been before. The necessity for rigidity has always been recognized, but the methods of securing it have not always been as well thought out as they should have been. On the Paige car the flange system is clearly illustrated, in which a substantial flange on the end of the starter housing bolts direct against the bell housing of the engine, giving a connection which is capable of withstanding the torque needs in cranking the engine.

A somewhat similar system to this is used in Packard, which is also bolted to the bell housing. On the Hupmobile this style of mounting is used for both the starting motor and the generator, with the starting motor bolting against the bell housing and the generator bolting against the front chain case. On the Oldsmobile a reversed system is used, with the starting motor mounted behind the fly-wheel to a flange on the clutch housing.

The practice of using the fan belt to drive other units is not confined to the generator. On the Oakland the water pump drive is also secured from the fan belt. On the Maxwell the pulley on the end of the camshaft drives the fan belt, which is also connected with the motor generator by means of a long shaft with a flexible coupling. This gives a triangular layout for the drive of the two members.

Various means of driving the distributor have been used successfully. Overland and Paige take the drive off the pump and generator shaft. In both these instances this same shaft runs continuously, forming the means of driving the fan pulley, distributor, water pump and generator. Very much the same idea is used by Dodge and Marmon, with the exception that the Dodge uses a motor generator and the Marmon a magneto. The drive is also similar in some respects on the Case 40, except that the fan pulley in this instance is not on the same shaft, but the generator and coil are located with the distributor along the side of the engine.

The Nash gives a very good example of compactness in drive, with the generator mounted on the camshaft, combining two units at that point, and the water pump mounted directly on the same shaft, doing away with any intermediate units at this point. The distributor is driven direct from the camshaft also, so that there is no exterior shafting nor any extensive timing gear set.

Choosing a Name Scientifically

IT would be interesting to know the circumstances which led to the adoption of many of the most popular and best known names in the motor car industry. The combination of initials which form a word is very common with the Italian makers, as witness F.I.A.T., S.P.A., S.C.A.T., etc. When the F.I.A.T. Co. was formed it was decided to adopt a title which would fully explain the nature of the business and the location of the firm, and *at the same time* to get such a combination of initials as would form a readily-remembered word. This was no easy matter, dozens of combinations being obtained without anything satisfactory being arrived at. The best combination appeared to be Fabbrica Italiana Automobili, the initials of which gave the word Fia. This was placed on the office wall, together with a number of others, with a view to soliciting suggestions from all comers. Probably the word Fia would have been adopted, when some stranger entered the office and wrote after the title the word "Torino," followed by a big interrogation mark. This was a happy thought, for the factory was being established in the town of Turin, and the four initials gave the word F.I.A.T., a word which is easily pronounced in all tongues, which is readily understood in all languages, and which most appropriately applies to a motor car. While a "Fabbrica Italiana Automobili Torino" car would have been just the same as a F.I.A.T., it is certain that the production would have been handicapped if it had gone forth with such an unwieldy title.

—

Philippine Tractor Need Grows

LONG continued ravages of rinderpest have reduced the number of carabas, the common beast of burden in the Philippines, and the continued expansion of agriculture in the islands is creating a good demand for a light farm tractor to sell at a reasonable price. Purchases of heavy tractors which sell at high prices will be limited to a few of the larger haciendas, but the market for light tractors for small planters and co-operative groups will be general. So far no such tractor introduced into the islands has been satisfactory. Manufacturers can reach this market either by forming connections with a machinery house now in business here or by sending their representatives into the field.

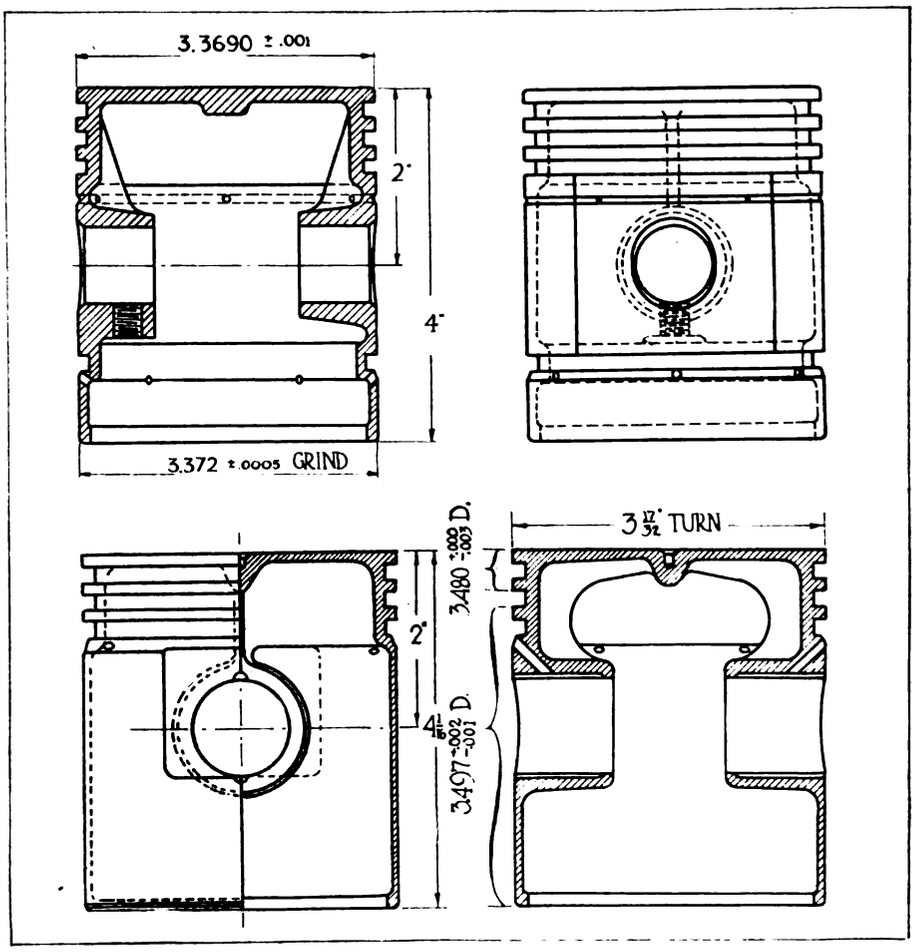
Piston Refinements Increase Weight

Tolerance Limits Are Close, Even in Commercial Practice of Large Production Companies—Limit of Lightness Passed

PISTON weights show no tendency to decrease further. Rather in a few instances the weights have been increased in order to secure additional stiffness. It would almost be indicated from this that the prominence given to light reciprocating parts led some of the engineers to rather overshoot the mark in this respect. One of the prominent eight-cylinder manufacturers in Detroit used pistons which weighed last year, at the beginning of the season, 15 oz., minus the wrist pin and rings. This company has been forced to increase the weight of these pistons, due to inability to obtain stiffness, so its pistons now weigh 1 lb. and 3 or 4 oz. This is a cast-iron piston.

It is also true that the aluminum pistons are being made heavier, and this is in line with aeronautical practice abroad, where the aluminum pistons are at least as heavy as cast iron, but are employed because of their ability to rapidly carry off a great quantity of heat. From all accounts, it would seem that the bottom of the weight scale in pistons was reached at the end of the year 1916, and during 1917 there has been a tendency to either remain stationary or go slightly upward.



For example, the Hudson company, which decreased the weight of their pistons to a noticeable extent until the end of 1916, at which time a weight of 30 oz. was reached, including rings, will now keep the same weight piston for 1918. On the other hand, the Cadillac company has added about 5 oz. to its piston weight. The weights of the Willys-Overland pistons as measured on Nov. 12, 1917, are given in the table herewith:

Weights of Standard Pistons

Model 89-6 H.A. 306		
Cast Iron Diam. 3½ In.		
1—2.06 lb.	1—2.12 lb.	1—2.04 lb.
1—2.08 lb.	1—2.06 lb.	1—2.04 lb.
Model 88-8, No. 26038		
Aluminum Alloy Diam. 3⅝ In.		
1—0.66 lb.	1—0.68 lb.	1—0.72 lb.
1—0.56 lb.	1—0.72 lb.	1—0.72 lb.
Model 88-4, No. 25596		
Cast Iron, Diam. 4¼ In.		
1—2.90 lb.	1—2.80 lb.	1—2.84 lb.
1—2.90 lb.	1—2.80 lb.	1—2.84 lb.
Model 90, No. 19277		
Gray Iron, Spec. No. 12 Diam. 3⅝ In.		
1—2.20 lb.	1—2.20 lb.	1—2.16 lb.
1—2.20 lb.	1—2.18 lb.	1—2.14 lb.

It is very possible, also, that a gain in weight has been due to the tendency to increase the number of rings to three at the top of the piston, or of adding a wiper ring at the bottom. This tendency has been caused by the trouble due to leakage of fuel past the piston rings as much as it has been to the desire to prevent the leakage of oil into the combustion chamber after the engine has become warmed up.

Another point on piston design which may be commented upon is the tendency toward closer limits. It would not be surprising to learn that this tendency is a development from airplane practice, because fits are certainly much closer since the art of building racing and aircraft engines has advanced. A sample of what is required in piston manufacture may be mentioned, the practice cited being that of one of the most prominent manufacturers of six-cylinder cars in Detroit. The piston, which is 3 11/32 in. in diameter, has a clearance of 0.0035 in. after running-in. The maximum out-of-round tolerance for lands and barrels is not more than 0.001 in. The diameter of the piston barrel must be maintained in relation to the diameter of the two top lands, with a tolerance of plus nothing and minus 0.001 in. The thickness of the walls and the wall under the ring grooves must be maintained within plus 0.005 and minus 0.015. The weight of the piston must be between 29 and 32 oz. The pistons are to be balanced in groups of six, and the variation between the heaviest and lightest must not exceed ½ oz. The piston pins have a maximum clearance of 0.0015 and a minimum of 0.0005.

Above—Typical piston which shows the tendency toward an increased number of rings. This has three above the wrist pin and a wiper ring below the wrist pin. Below—Section through the piston used in the Hudson 1918 *car*

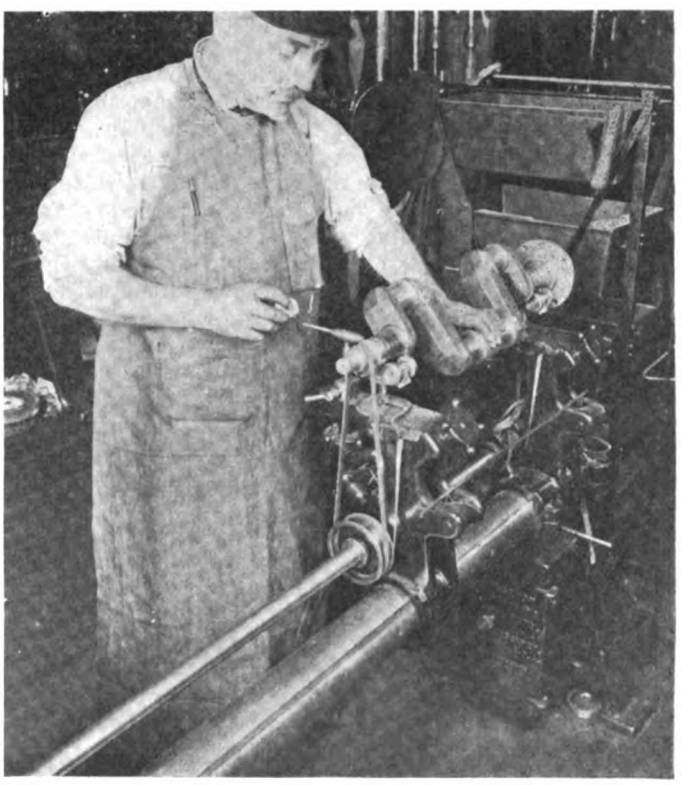
Commercial Crankshaft Balancing

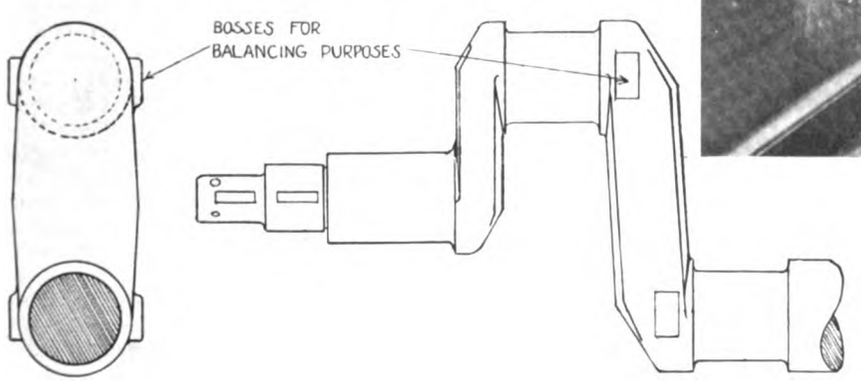
Machine Vs. Design Balancing of Crankshafts—Two Schools Not Influenced by Cost but by Engineering Belief

By J. Edward Schipper

WHEN the crankshaft balancing question began to assume serious proportions, due to increased rotative speeds, considerable discussion was started as to why the various methods suggested could not be put into practice on regular production jobs. At the present time this matter has been threshed out to two common methods, the first being where the dynamic balancing of the shaft is a part of its design and consequently no machine treatment is afterward necessary, and the second method where some type of machine is used to secure the dynamic balance. Manufacturers are divided between these two schools quite evenly in both the higher and lower-priced cars.



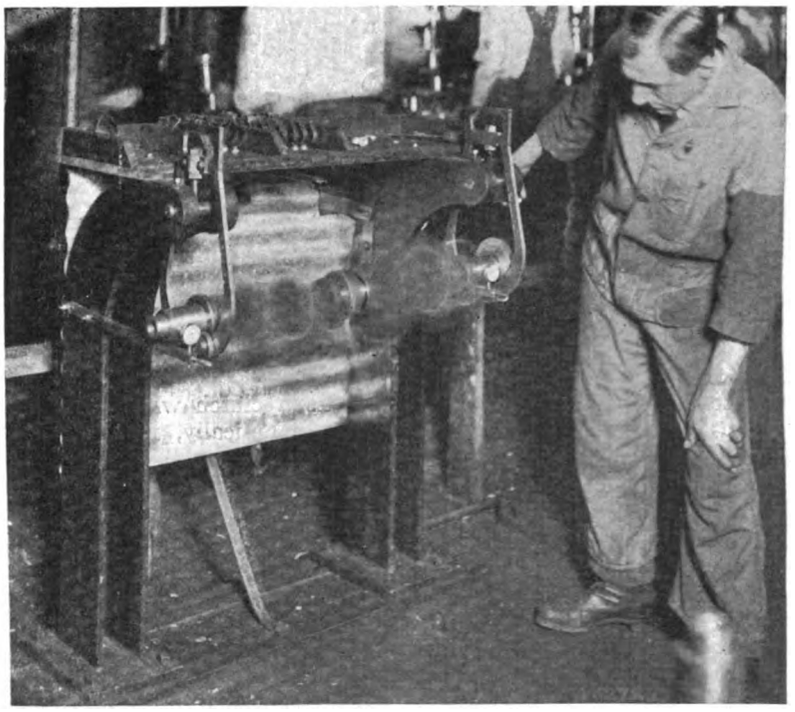
Packard does not use any balancing machine, but gets the shafts into proper running balance by machining them all over to very close limits. The theory is that after the balance is carefully figured in the design of the shaft and then the shaft is accurately machined to those figures, a perfectly satisfactory result will be secured. This type of engine, being a high-speed, twelve-cylinder design, representative of higher-priced cars shows that this is done not as a matter of cost, but because it is what is believed to be correct engine practice.



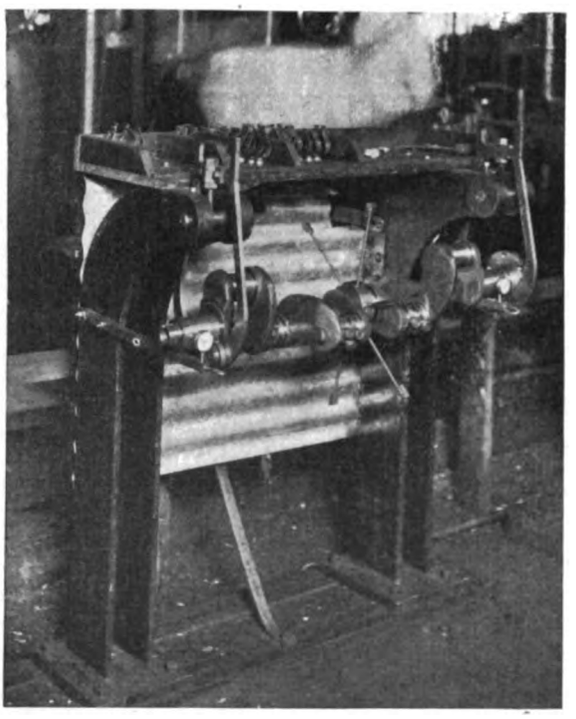
Maxwell Uses Design Balance

Another concern at the opposite end of the price scale which takes very much the same view of the situation is the Maxwell Motor Co. The Maxwell shafts are given only a static balance. During the process of designing the crank, however, the matter of dynamic balance was taken into account, and it was so constructed that it requires the removal of a very small amount of metal to bring the shaft into static balance. Since, theoretically, the inherent design of the crank is such as to bring it into dynamic balance, it is thought that the slight amount of metal removed to secure static balance does not affect this particular engine to any extent.

In the Hupp laboratory, experiments made by the engineering department have led this concern to doubt the practicability of dynamic balancing and also its usefulness upon touring-car engines. The reason for this as assigned by the engineering department is that the flywheel of automobile engines contains a clutch which is practically impossible to balance dynamically, for two reasons: First, because the parts of the clutch are not centered exactly with the crankshaft; second, because at least one element of the clutch does not maintain its phase with the crankshaft, but usually takes a different position every time the clutch is disengaged and engaged again.



The Hudson crankshaft is so well known that it needs no further discussion. It is built in accordance with the disclosure contained in the Fekete re-issue patent No. 14,292, and its balance is a matter of design and not of any special procedure in the course of its manufacture. On production jobs the Hudson company tests the crankshaft for static balance by balancing it on knife edges, but otherwise does nothing in the way of special balancing procedure. It is claimed that dynamic balance is maintained beyond the range of speeds of which the engine is capable.



Left — Drawing of the Willys-Overland crankshaft, showing how the bosses are left upon the shaft for balancing purposes. Above—Willys-Overland shaft placed in the Norton balancing machine being marked for excess metal

Digitized by Google

Left—Shaft being rotated in the Continental air-operated balancing machine. Right—Shaft in position in the Continental air-operated machine before air is turned on. The shaft is rotated by attaching a small paddle wheel on which a jet of air is played

Other manufacturers use machines in this work. The Studebaker Corp., for instance, uses a mechanical balancing method commonly known in the manufacturing field, the machine being the standard Norton balancing outfit. The Studebaker crankshafts, after forging, machining and grinding, are checked for alignment of bearings. They are then placed on the Norton machine and tried out for rotating or dynamic balance. The crankshafts are then marked as to where excess material should be removed, and upon taking off the desired amount of material, are again tested, the operation being repeated until the crankshaft is in balance. This method is stated by the Studebaker Corp. to be entirely satisfactory from both an engineering and production standpoint.

Very much the same method is used by Willys-Overland. The illustration herewith shows the application of the Norton machine in the Willys-Overland factory, with the workmen in charge marking on the shaft the place at which it is necessary to take off metal. The accompanying drawing of the Overland crankshaft shows the bosses which are left upon the shaft for balancing purposes. The desired amount of metal can be trimmed off these bosses without in any way impairing the strength of the shaft. They are ground down until the proper balance is secured.

The Oakland Motor Car Co. is using the Norton machine at the present time, but is experimenting on a new and original method of balancing, which will be described in an early issue of AUTOMOTIVE INDUSTRIES.

The method used by the Chevrolet Motor Co. is somewhat different. This concern has a fixture with four hardened and ground steel disks, which are about ⅛ in. thick on the outer edge and 5¾ in. in diameter. These disks are used as rollers on which the crankshaft is rotated while balancing. They are pivoted in pairs with center-to-center distance of pivots 3⅝ in., giving a pressure angle or contact point between the shaft bearing and the roller of about 45 deg. These two pairs of rollers are a proper distance apart to bring them in the center of the front and rear bearings when the crankshaft is placed upon them.

The shaft is thus tested for static balance, which must be within a limit of 1½ oz. This is obtained by means of a 1½-oz. weight which is held by spring-steel clips, the clip being sprung over the center bearing, bringing the weight 2 in. from the center line of the shaft, or in line with the center of the wrist pins, as on this particular design the crank has a 4-in. stroke.

The forgings are made with small bosses forged on either side of web or section of shaft between wrist pins, and when the shaft does not balance within the specified limit these bosses are ground off until the balance is restored.

An ingenious method used by the Le Roi Motor Co. is to suspend the crankshaft at one end by a flexible cord. The shaft is then rotated rapidly, and if it rotates accurately about its own axis, it is in dynamic balance. On the other hand, if it wobbles from side to side the ends are heavier than the center. If it tends to rotate so that its axis generates a cone about the point of suspension, it is heavier at the bottom, and if it tends to generate an inverted cone, it is heavier at the top. This method is cheaply installed and forms a good way of commercially balancing crankshafts.

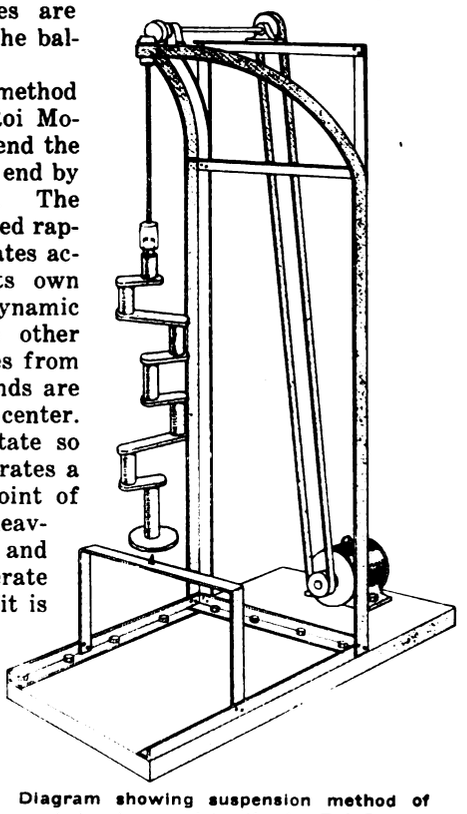


Diagram showing suspension method of balancing used by the Le Roi Co.

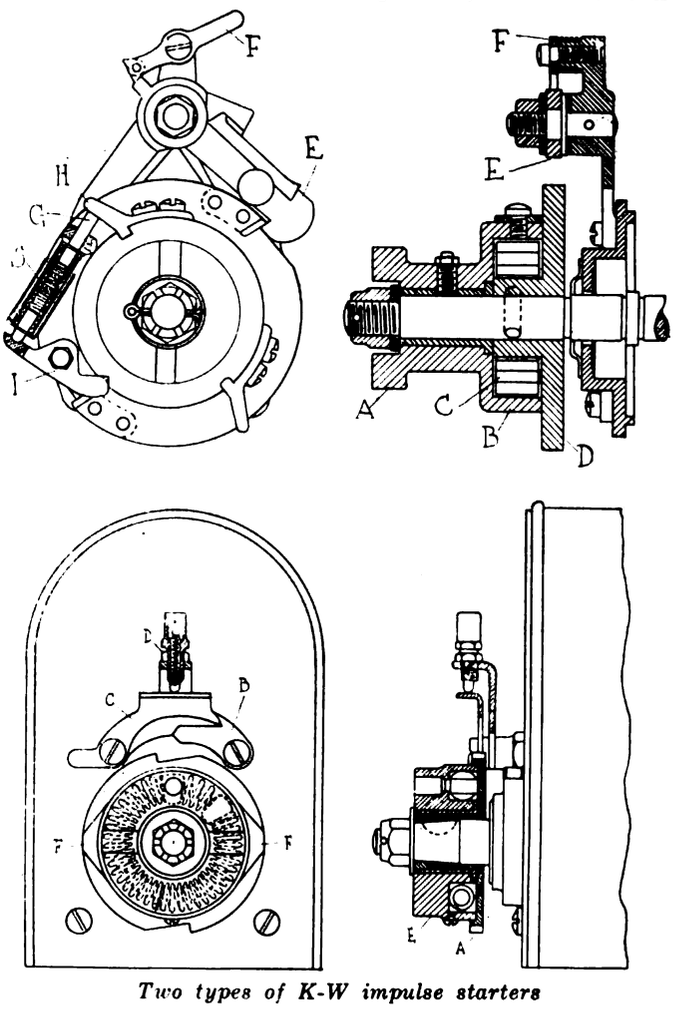
Impulse Starters for Tractors

Enable a Starting Spark to Be Obtained Without Spinning Engine—A Number of Designs Offered, Differing in Type of Spring Used and in the Form of the Detent Mechanism

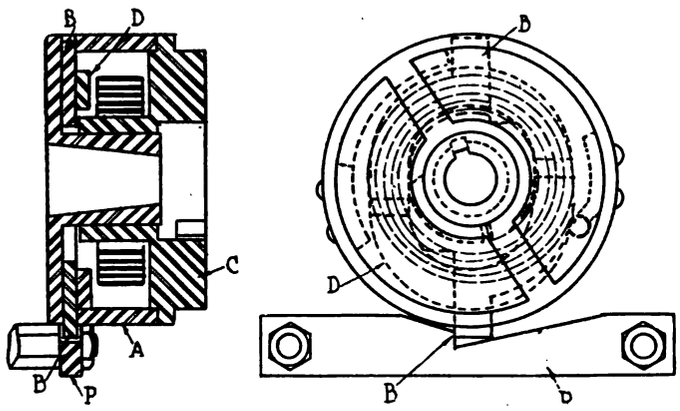
AT the present time magneto ignition is the accepted practice in tractor engineering. Tractor engines run up to very large sizes, which it is entirely impossible to spin by hand. A set of dry cells with some auxiliary mechanism would serve to give a hot spark even if the engine were cranked over very slowly, but ignition engineers familiar with the conditions under which tractors are operated prefer to do without dry cells. The inability of the ordinary magneto to furnish the one spark required for starting was certainly a great handicap in the field of slow speed engines, but magneto engineers did not let the difficulties attached to the solution of the problem involved stand in their way and produced magnetos which will generate firing sparks no matter how low the cranking speed.



Originally the alternating current ignition magneto was developed for automobile service, and an automobile engine can be cranked sufficiently fast to cause the magneto to generate a firing spark. Even so, it was much easier to start the engine on battery current, as this required merely turning the engine over the dead center, and in this country it became customary to use dual or double ignition, which combined the use of battery current for starting with magneto current for regular running.

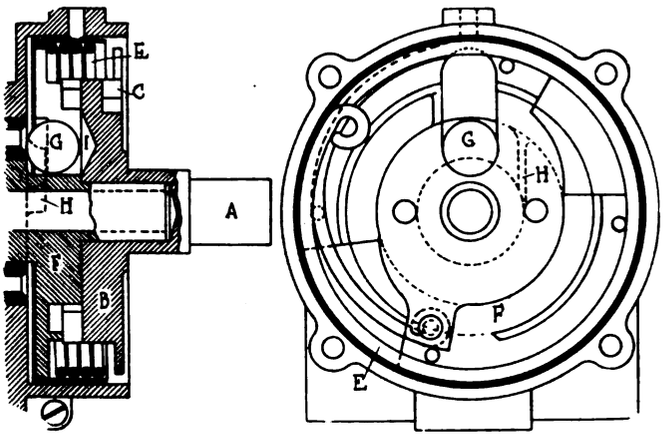
The problem of devising some means for obtaining a hot spark from a magneto at low speed first presented itself when this device was applied to stationary engines. These engines often run at such low speeds that a magneto geared to them in such a way as to produce no more than the number of current impulses per unit of time required to fire the charge would be operating at very low efficiency. The ordinary revolving armature magneto produces two impulses per revolution of its armature, and a single cylinder, four stroke engine requires only one spark every two revolutions of its crankshaft. Hence the proper gear ratio would be such that the magneto armature made one revolution to every four of the engine crankshaft. The impracticability of operating a magneto armature only a couple of inches in diameter at, say, 50 r.p.m. is quite apparent. It is, of course, the speed of the armature at the moment the circuit is broken that really counts, and not the average speed in driving the armature from the engine crankshaft at a uniform speed. The expedient was resorted to of partly rotating the armature in its bearings against the tension of a coiled spring, then suddenly releasing it by means of a tripping device and allowing the armature to flop back under the tension of the spring. In this way very considerable momentary armature speeds were obtained. The principle is made use of not only for starting but in regular operation as well.

For use in engines which in regular operation run at considerable speeds such a tripping mechanism would hardly be considered, because at higher speeds inertia begins to play an important part, and there are, of course, no inertia forces to be taken account of in a machine rotating at uniform speed. This applies to tractor work. The normal speed of tractor engines is quite sufficient to make it practical to drive a magneto directly, but the difficulty of cranking these engines by hand calls for a device whereby the armature speed can be momentarily accelerated when cranking. Such a device is known as an impulse starter and at present all of the magneto manufacturers catering to the tractor trade either offer such a starter or are working out the details of one.



An impulse starter is a device whereby the magneto armature can be held stationary in a certain position while a spring is being wound up or compressed by the motion of the engine; when the spring has been put under the proper pressure a detent operates and causes the armature to be accelerated by energy stored in the spring. This insures the necessary hot spark for starting. The detent device must be so designed that when the engine runs at normal speed it does not catch and the magneto is driven without change in the timing.

While at present impulse starters are used mainly on tractor engines, the first starter of this type, it seems, was designed for use on automobiles. At least some 10 years ago J. S. Bretz & Co. of New York imported a magneto known as the U. & H. which embodied this feature. Two views of this starter are shown herewith. The driving shaft *A* is formed with an integral disk *B* which at one point of its circumference carries a pin *C* to which one end of the coiled spring *E* is anchored. The other end of this spring is attached to a brass disk *F* secured to the magneto armature. Disk *F* is of irregular shape and is provided with a radial slot containing a steel ball *G*. When disk *F* turns right-handedly the steel ball *G* abuts against a projection *H* on the stationary armature housing. The result is that when shaft *A* is rotated, spring *E* is wound up, and this continues until a conical depression *I* in disk *B* comes opposite the steel ball. Then the ball drops into this depression, the armature is



Two types of K-W impulse starters

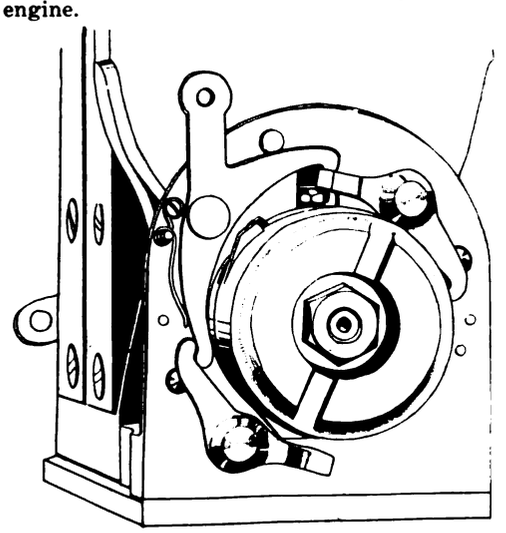
suddenly released, the spring unwinds and gives the armature a considerable speed, thus producing a relatively hot spark. The projection or cam *H* is so arranged on the circumference of the field pole circle that the unwinding of the spring begins when the armature comes into the arc of the greatest inductive effect. When the engine attains its normal speed the steel ball is carried to the outer end of the slot in disk *F* by centrifugal force and does not strike projection *H* in its rotation.



Probably the first American firm to get out an impulse starter was the K.W. Ignition Co. of Cleveland. The original K.W. impulse starter is shown on page 23. Combined with the clutch member *A* is a spring case *B* in which there is a spiral spring *C* whose ends are fastened to the spring case and to the ratchet disk *D* respectively. The latter is solid with the armature shaft, to which it is pinned. A pawl *E* pivoted on the magneto frame is adapted to engage into the notches on the ratchet disk *D*. On the circumference of the spring case *B* there are two knock-off cams *G* which when the spring case is turned while the ratchet disk is being held stationary will force the pawl out of the notch on the ratchet disk and release the latter. When once released the pawl is held out of contact with the ratchet disk by the lock F. As soon as the ratchet disk is released, it and the armature are spun rapidly by the spiral spring. As the engine is being cranked the clutch member *A* and spring case *B* are turning at a certain speed, but the ratchet disk *D* jumps ahead of the case *B* with the result that the knock-off cam abuts against a plunger *G* mounted on a cushion spring *S* on the ratchet disk. This same spring *H* serves to press the dog *I* into a notch in the outer surface of the spring case *B*. Before starting an engine fitted with this impulse starter the lock *F* must be pressed down so as to release pawl *E*. The reason for the double hook on pawl *E* and for two knock-off cams *H* turned in opposite directions is to adapt the starter for both right hand and left hand magnetos. The ratchet holds the armature back for a motion of the driving coupling of about 80 deg.

A somewhat different design of starter, in which a coiled spring is used to store up the energy for giving the impulse to the armature, is used by the K. W. Ignition Co. on its model T. K. magneto (page 23). In this model the ratchet disk *A* is held from rotating by pawl *B*, which can be held out of contact with the ratchet disk by catch *C*. A spring pressed plunger *D* normally holds the catch in engagement with the pawl. As in the previously described model, the coupling members and spring case are formed in one unit *E*, which is turned with a groove in its face in which the coiled spring lies. The spring is located between two stops, of which one is secured to the ratchet disk and the other to the spring case. There is a second small spring, acting as a buffer spring, which fills the rest of the channel in the spring case not occupied by the main spring. This buffer spring takes up the reaction when the ratchet wheel is released and the armature snaps forward. Disengagement of pawl *B* is effected by means of cam lobes *FF* on the outer surface of part *E*. The pawl is made of sufficient width so that its nose may engage both the ratchet wheel and the cams.

Another impulse starter is the Kingston made by the Kokomo Electric Co. Referring to this design the ratchet or slotted part is stationary and the pawl revolves. The sectional view shows the spring to be of the flat spiral type. The hub of the spring housing *A* is turned out to a taper to fit the magneto shaft. There is a double pawl, the teeth *BB* of which pass through slots in the outer wall of the spring housing. One end of the spring is secured to the housing and the other to the clutch member *C*, which latter has a hub telescoping the hub of the housing. Secured to the pawl is a cam *D* which is acted upon by a detent device carried by the coupling member. When the coupling member begins to turn, the spring housing being held from rotation by the pawl, the spring is wound up. Gradually the detent device works up the slope of the cam, and when it reaches a certain position the pawl is withdrawn from the notch in the catch plate *P* and the armature jumps ahead.

The Swiss Magneto Co., Monroe, Mich., manufactures an impulse starter which gives two impulses per revolution of the magneto if desired. In this device use is made of a flat helical spring. There are two main parts to the coupling, one keyed to the magneto shaft and the other telescoped over the hub of the former. A bracket screwed to an extension of the magneto base carries the detents and the lever for settling same. When power is applied to the Oldham coupling member while the detents are set, the spring is wound up until the cam on the coupling member releases the detents. Then the armature is spun forward. This causes a post on the coupling member to be engaged between a stop and a dog on the ratchet wheel, so that the timing cannot vary when the engine is running at normal speed.

From the detent lever connections can be made to any part of the machine, so the operator need not raise the hood to set the detents. As long as the driver pulls on this lever the impulse effect is obtained; hence the detents must be released as soon as the engine is started, as unnecessary use of the impulse device simply wears it and reduces the power of the engine.

The War's Effect on the Industry

Economy Will Be the Keynote of Design—Miles-Per-Gallon a Greater Criterion Than Miles-Per-Hour—Excessive Flexibility Demands Must Be Dropped—Cheaper Grades of Fuel Will Have to Be Used

By A. Ludlow Clayden

War's influence on automobile design and on automobile merchandising was the general topic of discussion at the December meeting of the S. A. E. Metropolitan Section held at the Automobile Club of America on Thursday evening, Dec. 27. Of the two papers of the meeting, one, by A. Ludlow Clayden, engineering editor of AUTOMOTIVE INDUSTRIES, *is reprinted herewith. The other paper, How the War Will Affect the Automobile Dealer, was by Ray W. Sherman, editor of Motor World. A number of prominent New York dealers were present and took part in the discussion.*—EDITOR.

THERE are hardly any prophets left who will venture to predict the duration of the war. Lacking any definite ideas on this subject it is hard to anticipate the effect of the war on the American automobile industry in the ultimate. To make any sort of an analysis it is necessary to assume that the war will last a substantial time, a year or more at least.

If the war does not end before Dec. 27, 1918, the passenger car industry of this country will still be one of the greatest industries of the U. S. outside of munition making, which will be temporary. It will maintain its position because America is the world's automobile factory, just as China and India are the world's tea centers, just as Brazil is a coffee center. The United States is the logical place for the manufacture of the bulk of the world's supply of passenger cars, and as long as that is true, just so long will passenger car making be one of the mainstays of American trade.

War is having an effect upon every last detail of civilized life, and it is going to affect automobile design just as much as other things. We are to-day entering an era in which the highest ideal of a man or of a nation is the ideal of economy. Never before in history has economy been more admired than extravagance, never before has a change in public sentiment been made so swiftly. The American nation, a leader in so many things, has for fifty years been proud of the fact that its resources permitted it to be a leader in extravagance. Like the wealthy man who demands the best of everything, America has been the wealthy nation able to pay for whatever it wanted.

Now this is all changed. The admired man to-day is he who, though able to spend on personal gratification, holds back and contents himself with something smaller, giving the balance to the vital needs of the day. This is not only a temporary condition to end with the war. It is a condition which will last long after the war is over, a condition which is being impressed so strongly on the minds of the now adolescent generation that it may well become the ruling spirit of the next hundred years.

If these premises are sound, then the American passenger car of the near future is going to be one in which economy is a strong feature. A car of which the first cost, plus the maintenance cost over a period of years, will make a good showing. We are about to exchange "what will she do on high?" for "what will she do to the gallon?"

IT IS A FACT THAT ALREADY THOSE CARS WHICH HAVE A REPUTATION FOR ECONOMICAL OPERATION HAVE SUFFERED FAR LESS THAN THOSE WHICH ARE KNOWN AS WONDERFUL PERFORMERS.

The volume of passenger car business being done today represents little more than the essential trade which supplies transportation to those who need it. The whole agricultural life of the whole United States and a good half of the business life of small towns and large cities depend today upon passenger car transportation. The farmer's timetable of his week's work is laid out on a schedule that necessitates a car to get him from point to point. And on the city side, just imagine, say, Philadelphia bereft of passenger cars. Think of the utter impossibility of living in Philadelphia's residential districts without road transportation.

THE LAST TEN YEARS OF AMERICAN TOWN PLANNING HAS BEEN ON AN AUTOMOBILE BASIS.

THE AMAZING INCREASE IN AMERICA'S AGRICULTURAL OUTPUT IS DUE TO THE RAPIDITY OF GROUND COVERING PROVIDED BY THE AUTOMOBILE.

But the average American car has exacted too high a price for the service it rendered. Not too high a first price, but too high a maintenance price. It has been too big, too heavy, too powerful; too extravagant of fuel, of oil and of tires; too frequently in need of repair.

To take just one instance: it is absurd to utilize two tons of machinery to carry a man ten miles from his home to his office. It is equally absurd to provide his car with an engine which normally has a fuel efficiency of 10 per cent, when it could have a 20 per cent efficiency by sacrificing the ability to crawl on high gear.

I do not wish to quote the European example as in any sense a criticism; but it is true that European cars have been much less costly to operate. They have to be because of the much smaller average wealth. The English or French user simply had to consider running expense. He had to have an economical car or none. This is the reason why motor cycles have had such an immense vogue on the other side of the Atlantic. The average American says "*I* can't ride a motor cycle." "It isn't in keeping with my position; my friends would roast the hide off me." True enough last year—but will it be true next year?

Similarly it has been an ideal to have a huge car, an ideal fostered by advertising and by salesmen everywhere. Without doubt the big car has its comforts, but the little car has conveniences which more than counterbalance. Nobody who has tried both would ever choose a 140-inch wheelbase car for shopping in preference to a 110-inch one, provided both were of the same standard of engineering. At present engineers then have two ways to work—one towards a car which is more economical because it is smaller; another towards a car which is more economical because it is inherently better.

It is just a personal opinion, perhaps worth quoting in passing, that the greatest trade open to a magnetic system of transmission is in a car with about 110-inch wheelbase, a 200-cubic inch engine and made in a quality which will make its fair price around $2,000.

There is another thing. We are nearly at the end of gasoline as we know it. No doubt the fuel ten years hence will still be called gasoline, but it will not operate a 1918 gasoline car. We have got to learn to sacrifice the absurdities of "flexibility" existing in the modern engine in order to use a fuel which we will be able to buy for a third the present price. There is nothing to prevent a man lighting cigars with dollar bills if he wants to, but the world at large thinks it silly when matches are so cheap. At present the automobile is running on dollar bills instead of dimes, with little more real reason.

Scotland Favors Light Farm Tractors

Demonstrations Show That This Newer Type Machine Is More Suitable for Routine Farm Work Than Heavier Ones

EDINBURGH, SCOTLAND, Dec. 11—The following is practically the complete report of the special committee in conjunction with the three tractor demonstrations held in Scotland last October. The first of these demonstrations was held in Edinburgh, Oct. 17 and 18, the second at Glasgow, Oct. 22 and 23, and the third at Perth, Oct. 26 and 27. The following report is based on conclusions arrived at by the committee in conjunction with all three of these tests. In reading the report it should be borne in mind that relatively small areas were plowed due to the difficulty of securing large areas. The conclusions of the committee were published in a recent issue of AUTOMOTIVE INDUSTRIES.

The following is the report:

The committee was instructed, in preparing the official report on the demonstration, to give special attention to the following points:

a—Weight of machine.
b—Mechanical design and construction.
c—Quality of work.
d—Time taken and attendance required.
e—Adaptability for plowing different widths and depths.
f—Adaptability to various kinds of work, such as cultivating, harvesting, road haulage, and the like.
g—Ease and safety of handling.
h—Ease of turning, and space and time required for same, and uniformity of furrow ends in plowing.
i—Facility and efficiency of attachment of tractor to plow other farm implements.
j—Price.

Nature of Ground

The ground at the first demonstration consisted of a deep free loam, with occasional earth-fast stones. Part was in lea, part in stubble, and from part a potato crop had been taken. On the two larger fields, one of stubble and one of lea, there was a gradient, reaching at its steepest part 1 in 7. This gradient, which averaged about 1 in 12, occurred nearly equally throughout all the plots.

At the second test both stubble and lea were provided, but on account of extremely wet weather before and on the days of the demonstration it was found impracticable to attempt plowing of stubble. The lea field consisted of tough old grass land, which when last plowed had been set up in ridges, thus increasing the difficulty for multiple plows carried on frames which are adjusted by wheels. The gradients were not severe.

The ground at the third test consisted of a free loam overlying a clay subsoil, and was somewhat shallow on part of the rising ground. Both lea and stubble were provided. The lea field was practically level, as was also one of the stubble fields, although on this latter the conditions were rendered somewhat more severe through dung being spread on the surface. On two other stubble fields there were stiff gradients, averaging about 1 in 9, and reaching a maximum in places, and for short distances, of 1 in 5.2.

As there was a large number of entries, and it was desirable, for the convenience of visitors, that the machines should be seen at work within as small an area as possible, the plots laid off were smaller than might otherwise have been considered desirable. These varied in extent from about three-quarters of an acre to about two acres.

Prior to the demonstration, feerings were drawn by horse plows, and headlands were marked off twelve yards in width. At Edinburgh and Perth the system of plowing was entirely winding or scaling—*i.e.*, the tractor was required to plow out the land which lay between the feerings which bounded its plot. At Glasgow the machines were required to gather to the feering, which was in the center of each plot.

Conditions and Regulations

Exhibitors were left as free as possible to demonstrate the capabilities of their machines in the manner they considered most suitable. No restrictions were imposed as to the plow to be used, the number of furrows taken, or the speed of the tractor. The depth of plowing was, however, prescribed, and varied at the different centers from 6 in. to 8 in. for lea, and from 7 in. to 9 in. for stubble. Any machine which failed to plow to the required depth, or which was unable to perform the work to the satisfaction of the stewards and committee, was prevented from proceeding until the fault had been remedied.

Twenty-nine tractors took part in the demonstration. The number of plows was considerably greater, as several tractor exhibitors sent more than one plow, and a number of plow-makers entered plows independently. The report gives a detailed description of the machines, alphabetically arranged according to the names of the exhibitors, and then states:

Classification of Machines

The twenty-nine machines which took part in the demonstration may be grouped according to the following classification:

Wheels—
15 ran on 4 wheels.
6 " " 3 "
4 " " creeper tracks.
4 were single-unit machines (1 with creeper).
—
29

Attendance—
11 were handled by 2 men.
18 " " " 1 man.
—
29

Fuel—
25 were driven by paraffin.
3 " " " gasoline.
1 was " " steam.
—
29

Weight—
2 weighed 8960 lb. and over.
3 " 6720 " " "
6 " 5600 " " "
7 " 4480 " " "
3 " 3360 " " "
8 " under 3360 lb.
—

Report by Official Observers

The decision of the directors that the demonstration should not be regarded as a competitive trial precludes the Reporting Committee from making any attempt to arrange the vari-

Digitized by Google

ous tractors exhibited in any order of merit. Even apart from this, however, they do not believe that the circumstances and conditions of any such demonstration would make possible any final judgment on the merits of various types of machines, since very important considerations could only be determined in a much more extended period than that which was available.

But while the committee cannot properly make such a report as would definitely advise intending purchasers in the choice of a tractor, they believe that the observations which follow may be useful in this direction, as well as in suggesting to engineers important respects in which agricultural tractors and plows may be made more useful in tillage operation.

Weight

With regard to weight, it will at once be apparent that, in many cases, the tractors shown have been evolved on the lines of the heavy steam tractor. The most noteworthy feature of the present demonstration was the appearance of the light land tractor constructed on new lines. Several manufacturers appear to have departed from the idea that great weight is necessary for a tractor to do efficient work on the land. It was clearly shown at the demonstration that light machines, adequately provided with spuds, grip the ground and perform the work better than the heavier machines. Every drawback, such as slipping in soft land and inability to climb gradients, was aggravated by increase of weight above a certain limit. Extra weight also increases the risk of breakages where stones are encountered, and the danger of injury to the land through compression, this being very noticeable during the demonstration, especially when the driving wheel on the land traveled within a few inches of the previous furrow. Besides this, a heavy tractor is at a distinct disadvantage for the other and lighter forms of cultivation, such as grubbing, cultivating, seeding, and harrowing, and also for harvesting, especially where the land is sown out with grass seeds.

The light tractor is quite suitable, not only for plowing, but for these other farming operations, and therefore embraces all the usual requirements of a farm tractor, including the driving of a threshing-mill and other farm machinery. It should be kept in view that for heavy stationary work proper anchorage must be provided. The only class of work for which the light tractor does not appear to be suited is road haulage. For road haulage weight is a necessity, as spuds cannot be used to give the necessary gripping power.

This leads the committee to the conclusion that field work and road work are more or less incompatible, and that a light tractor, such as is suitable for land work, is not so useful for road haulage. In addition, for road work, a tractor should be sprung to minimize the vibration, while for field work springs are undesirable, and only entail extra weight.

The committee have come to the conclusion that, to suit conditions in Scotland, an efficient land tractor need not exceed 3360 lb. in weight. In point of fact, several of the tractors which did excellent work at the demonstration were well within that weight.

Horsepower

While, at the demonstration, the machines were shown in the hands of experts, it is generally recognized that under ordinary farm conditions the driver of the tractor may not be able to obtain the maximum output of power, and that for this reason a substantial reserve of power is highly desirable. It must be kept in view that under unfavorable weather conditions considerable waste of power will occur through the softness of the ground and extra friction due to the clogging of the wheels and moving parts with mud, stubble, and manure.

For these reasons the committee is of opinion that for general farm work a tractor should have ample engine power, and they consider that to give the necessary margin of safety 20 B.hp. is the minimum.

In arriving at this conclusion they have in view that the tractor should be capable of hauling a plow taking two full furrows under the worst conditions, and three furrows under favorable conditions, and should also be capable of driving a 4 ft. 6 in. threshing mill.

As stated above, five tractors, embodying a caterpillar track arrangement, were shown.

While this arrangement undoubtedly distributes the actual dead weight, and thus reduces the intensity of pressure on the land, it appears certain that there must be excessive wear and tear on the creeper.

As far as the committee was able to observe, the creeper machine has not been shown to have any advantage in gripping power over the best type of wheel machine, and when it has to encounter a stiff gradient on greasy land it is very liable to slip.

Spikes, Bars and Spuds

The various devices used for giving the wheels the necessary grip of the land may be classified into three groups:

1. Spikes—either round or square in sections.
2. Bars—varying in length and in the angle at which they are placed on the rim of the wheel.
3. Spuds—mostly rectangular in section, and about 3 in. or 4 in. in width.

With regard to spikes, the committee is of opinion that on soft land these do not give sufficient gripping power, and they are also liable to bend or break. Bars, on the other hand, are open to the serious objection that when their width approaches the width of the furrow they cut the turf into sections, and thus seriously interfere with the proper turning of the furrow. Where very long bars are used this drawback is particularly noticeable, and the effect is greatly to impair the quality of the work done. On the whole a stout spud 3 in. to 4 in. in width and from 4 in. to 5 in. in length appears to be the most satisfactory, especially when these spuds are so arranged, in relation to the circumference of the wheel, that the full gripping power of one spud, or its equivalent, is always in operation.

Accessibility and Protection

The committee noted that considerable attention had been given to rendering the vital parts of the machinery more accessible, and also to providing protection from the effects of bad weather. It should be kept in view that tractors require to be left in the fields, where they are exposed to the weather and to the danger of being tampered with by the public, especially in populous districts, and makers should therefore aim at the provision of complete protection. It would also be an advantage to provide some protection for the driver.

Brakes Are Needed

It is desirable, especially for transport purposes, that all tractors should be provided with adequate brakes.

Reliability and Durability

In a demonstration such as the present little opportunity is afforded of forming any definite opinion as to reliability and wearing qualities of the machines. The fact that only one tractor of those which started failed to complete the six days' work seems to indicate that a fair degree of reliability has been obtained, especially considering the amount of shifting and railway transport which the machines had to undergo. In this connection it should be kept in view that the demonstration was a fairly severe test. At the demonstrations there were few machines which did not encounter earth-fast stones on some part of the ground, and that without incurring any serious injury. At the second demonstration the weather was of the severest kind, and the ground was consequently in a very bad state. At the third test a feature of the trials was the gradient on the stubble fields, which was as steep as 1 in 5.2 for short distances in one or two places, and a considerable part of which averaged 1 in 8 or 9. These gradients were successfully negotiated by several of the tractors, even although the ground was in a soft condition.

Two defects may be mentioned as tending to impair durability. These are the exposed gear drives on some of the wheel tractors, which fill with mud and grit, and the already mentioned excessive wear associated with the caterpillar arrangement.

Spring and Other Connections

The committee observed that many makers now recognize the necessity of making some provision for minimizing the

Digitized by Google

effect on the plow of striking an earth-fast stone. This took the form, in most cases, of a device embodying a wooden peg, which shears on being subjected to undue tension, thus carrying out the principle of the weakest link. This appears to be a somewhat crude arrangement, particularly as it fails to act as an absorber of minor shocks. The committee is of opinion that the drawbar should be provided with some spring appliance, which would relieve the strain on the plow in the case of encountering minor obstacles. With this might be incorporated a release device, which would completely detach the plow under the strain of a heavy shock. The committee suggests that this attachment should be an integral part of the tractor, and not merely a casual device inserted in the draught connections.

It was also observed that while sufficient provision was made for alteration, in a horizontal direction, of the point of attachment of the plow to the tractor, in few cases was provision made for shifting this point in the vertical direction. This is of importance, as for different implements different heights of attachment are required, and even for plowing it was observed that, in some cases, the point of attachment was too low, and there was no means of raising it.

Best Speeds

On the whole, the speeds provided by the makers of the various tractors appeared to be suitable. Most were provided with at least two speeds forward and a reverse. For consistent good work in plowing, any speed exceeding 2½ cr 3 miles an hour is excessive. This would also apply to mowing and reaping. For spring cultivation a higher speed is desirable. The committee therefore suggests that speeds of 2½ and 4 miles per hour should meet the requirements of a tractor for use on the land.

The Fuel Situation

It is to be regretted that it was found impossible to carry out any test of fuel consumption in connection with the demonstration. As the question of fuel consumption is of great importance, it should be explained why this was not done. There are two ways in which fuel consumption may be measured:

1. By emptying the tank of the tractor, filling in a definite amount of fuel and noting the work accomplished on that amount.

2. By completely filling the tank, and, after a definite amount of work has been accomplished, refilling and noting the amount of fuel required to refill, which will give the measure of the amount consumed. Both of these plans presented serious difficulties. In the case of the first there was the difficulty that many of the tractor tanks could not be completely emptied. In that of the second the amount of fuel required to fill completely all the tanks, some of which had a capacity of 20 or 30 gal., was such that, under present conditions of fuel supply, it could not be undertaken. In addition to these, there was the difficulty at this time of providing a sufficient number of trained observers to accompany each machine throughout the duration of the test.

Other factors which would tend to render such a test unreliable were the variations in the character of the soil and in the type of plow used, together with the fact that the duration of the demonstration was not sufficiently long to provide time for a reliable consumption test.

The committee formed the opinion that the carbureters on many of the tractors were not capable of thoroughly and completely vaporizing kerosene, and that consequently the combustion in many cases was defective, and the haulage power of the tractor seriously impaired. It may be found, when normal conditions return, more satisfactory to use gasoline rather than kerosene, as being more efficient, even although the price be somewhat higher.

Plow Defects

While some of the plows did excellent work, speaking generally, the work of the plows was much less satisfactory than the work of the tractors. Where a plow expert was in attendance, the plows were soon adjusted to suit the land conditions; but in most cases the man in charge of the tractor, not being a plow expert, was content to devote his attention to the tractor, with the result that the work done was far from satisfactory. Many of the plows, and especially those of foreign construction, were unsuited to perform the work as required in this country. The lack of means of adjustment to varying widths, so as to suit the depths and the class of work, was a conspicuous defect. The furrow slice turned by some of the plows was too wide for work on lea, and perhaps too wide also for early stubble plowing on stiff clay soils. Makers should note that merely turning over the land will not suit Scottish conditions for autumn and winter plowing.

It was further noted that many of the plows which did good work on stubble did unsatisfactory work on lea. If the same plow is to be used for both lea and stubble, it must be made adjustable as regards width of furrow from, say, 8 in. to 12 in.

It may, however, be found more advantageous to have two plows, and that for the following reasons:

1. The provision of means of adjustment may be found to affect the rigidity of the plow, while only providing to a limited extent for the double operation; and

2. The power-drawn plow, being an important farm implement, its breakdown is a serious inconvenience, and therefore it is desirable to have an extra plow in case of emergency.

Many Automatic Lift Plows

For plowing lea, with rough grass on the surface, the plow should be fitted with a disk coulter and skimmer to cut and turn in the grass.

Many of the plows were fitted with automatic lifts, which had the effect of making the tractor and plow a one-man outfit. This is a matter of prime importance, and demands the attention of all plow-makers.

One defect of the automatic lift as seen in operation—where the raising mechanism is operated from the plow wheels, and therefore depends on the forward motion of the plow—is that a plow cannot be lifted while the machine is stationary. That defect is overcome by the power-lift shown on one of the tractors, where the plow is lifted bodily out of the ground by a crane-like mechanism operated direct from the engine.

Another defect noted in some of the plows of foreign make was the absence of any device for regulating the width of the leading furrow, with the result that the position of the tractor affected the size of this furrow, and consequently, where steering of the tractor was not carried out with care and precision, the size of the leading furrow varied to such an extent as completely to spoil the appearance of the plowing. Tractors which had the guidance of one or more wheels in the furrow had an advantage in this connection. Plows with a guide-wheel in the furrow entirely overcome the difficulty, as the width of the leading furrow can be regulated to the same size as the following furrows.

Two suggestions with regard to tractor plows occur to the committee:

1. If the last unit of the plow could be made so that it could be thrown out of action by being raised by means of a lever or otherwise, it would give the option of plowing, say, two furrows on an up gradient and three on a down.

2. The introduction of a one-way plow would obviate the necessity of having feerings and finishes, most of which, under present circumstances, must be performed by horses.

Handling and Turning

At the demonstration all the machines were cleverly handled. The demonstrators were, of course, experts, but it did not appear that the management of the tractors presented any great difficulty to an intelligent man. There also did not appear to be any danger of personal injury associated with their use, provided reasonable care is taken.

The single unit machines had the advantage that the implement operated was directly under the observation of the driver; and the principle is worthy of commendation, especially having regard to its usefulness in other farming operations.

Ample headlands, measuring 12 yards in width, were provided for turning. Some of the larger outfits took the whole

Special Spark Plugs Needed for Airplane Engines

1 Usual Insulating Materials Seldom Withstand Heat
2 Electrode Must Be Specially Cooled
3 Oil Must Not Reach Insulation or Must Be Burned
4 Plug Must Have Good Mechanical Strength

THE writer of this article has been engaged in spark-plug investigation for one of the allied governments. His experience is exceptional, and the ideas in the following are based on much practical work in conjunction with spark-plug testing.—Editor

THE question of producing spark plugs of a quality satisfactory for the severe conditions to which these are subject on the modern highly developed aviation engine, is getting more imperative as the engine development progresses.

In spite of the response from manufacturers in this country and abroad and in spite of the large amount of development work that has been made, indications seem to prove that the spark-plug development has fallen behind rather than followed the engines.

The problem is unfortunately not solved by producing a spark plug that is satisfactory for all engines in production to-day, as a new engine development may come along at any time which may call for still higher qualities in the spark plugs. The fact that the engine must be constructed first, before the spark-plug requirements can be studied, is the natural cause for the lag in the spark-plug development. As, however, the speed of development and progress is accelerating for every day that goes, the lag in the spark-plug development is felt more keenly and the necessity of following up with this cannot be sufficiently emphasized. The deciding factors which determine the construction of the spark plug are heat, oil conditions and gas tightness, in addition to which comes insulation qualities under heat of the insulating material used.

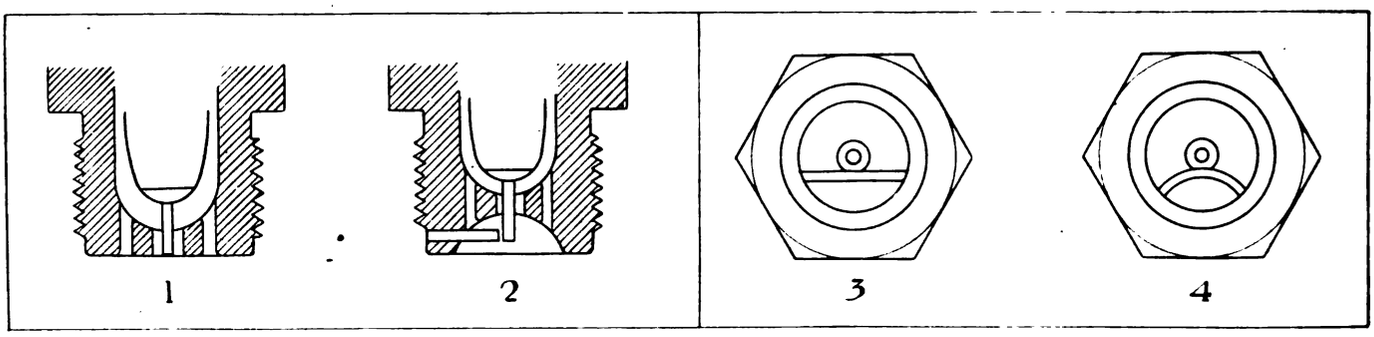
Why the Service Is Severe

It is not always evident to the layman why the service of the spark plugs on aviation engines is so much more severe than on automobile engines. Nevertheless, there is to-day not a single automobile spark plug in use in the air service which has not undergone considerable changes in material or design. The difference can, however, easily be comprehended when a rough comparison is made.

The average automobile spark plug has proved entirely satisfactory on the average automobile and the life of a well-made spark plug has been practically unlimited. The average speed of a touring car is probably not over twenty miles an hour and the corresponding engine speed averages approximately 1000 r.p.m. This is furthermore intermittent service. A touring car will hardly ever travel at the rate of 40 m.p.h. for a period of over four or five minutes without slowing down, passing other vehicles, curves, etc. On the aviation engines the spark plugs are called upon to operate hour after hour at an engine speed of 1800 to 2200 r.p.m., without a minute's let up—without a drop of as much as 20-30 revolutions. The effect of this continuous high speed can hardly be understood if it has not been seen in practice.

However, experience has proven that a drop of 10-20 per cent in engine speed for a few minutes will allow the spark plugs to overcome some of the fatigue to which they are exposed and prolong their life for a time period many times as long as the period of rest that was given them. On engines where the spark plugs are subject to severe conditions, their life may be a few hours on continuous run under full load, while it may be ten times as long if the engine is run at 75-80 per cent full power. From this it is better possible to understand the excellent service obtained in automobile practise from a number of different makes of spark plugs. Even in racing practise we find that the least retardation while turning the curves of the track is sufficient to offer the spark plugs a period of rest that materially increases the length of their life. This is only one factor in the spark-plug service, which, however, in itself proves the distinctive difference in the operating conditions. Other factors such as compression and heat must also be taken into consideration.

Compression Conditions Differ



The compression on the average car is 70-80 lb. per sq. in. when the engine is new, but in most cases this falls rapidly when the engine is slightly worn and 50-60 lb. is undoubtedly nearer the average of cars in actual use. The compression of the aviation engine has steadily been increased during the past few years and goes now as high as 120-130 lb., and it must be kept in mind that this compression is practically maintained throughout the life of the engine, as this is ordinarily overhauled for every 50 hours of actual service, and all worn parts replaced.

The local heat in the insulation body of aviation spark plugs is high, due to the increased number of explosions and the high mean effective pressure in connection with the poor heat-conducting qualities of most of the insulation materials which are adaptable for spark-plug construction.

In studying the construction of the spark plugs we find that there is a number of different conditions that must be met, and which again largely depend on the material used for the insulation bodies. The main requirements will be stated first followed by a brief discussion of the ways and means of meeting these.

The requirements are:

Digitized by Google

Some of the different constructions commonly used in airplane engine spark plugs

(1) Gas tightness.
(2) Mechanical strength.
(3) Self-cleaning qualities.
(4) Minimum electrical leakage.
(5) Temperature resistance.
(6) Absence of preignition.

Perfect gas tightness is very difficult to obtain, on account of the different temperatures to which a spark plug is subject; temperatures which are not uniform throughout the various parts of the plug. Where different parts are assembled by means of mechanical joints such as compression nuts or spinning operations, it is evident that different temperatures cause different expansion of the various parts and tend to produce gas leaks. To overcome this it is necessary that the joints are compressed to such a degree that there is danger of setting up stresses on the insulating body, which may prove fatal to this and cause mechanical breakdown.

Obtaining a Gas-Tight Joint

A more satisfactory way of producing a gas-tight plug is to use an insulation body that can be brought into chemical connection with the metal parts. Such has been done by "welding" a glass body into the steel shell. A joint of this kind will stay tight under all temperatures encountered in actual service. The success of such a construction depends, however, entirely upon the characteristics of the glass composition. The spark plug must, unless the melting temperature of the glass is high, be designed so that the glass will remain very cool under operating conditions. This, however, allows oil and carbon to collect on the surface of the glass without burning it off and thus destroys the self-cleaning properties of the plug.

The cemented joint, which appears around the center electrode in the conventional design of porcelain plugs must be made with great care. Some cements that have been used successfully for a number of years in automobile practise have proved to soften and melt when exposed to the high temperatures of an aviation engine. Others seem to loose their body and drop out as a powder, thereby exposing cavities inside of the porcelain. The pressure in these cavities will increase with every compression and explosion stroke, and will again decrease with the intake stroke, thus causing hot gases to flow back and forth and produce excessive local heating of the porcelain. This will result in an uneven expansion and crack the porcelain in a very short time. Local heating, caused by leakage or cavities, is the main reason for the strict requirement of absolute gas tightness, as the effect is the same if a leak occurs at any place around the gasket seat of the insulation body. The loss in compression, due to a small leak in the spark plugs, is negligible and not in any way to be compared to the importance of the effect on the insulation body.

Mechanical strength of the insulation body plays an important part, as a great mechanical strength will allow a high pressure to be used in the joints and consequently resulting in a tighter spark plug. The location of the spark plugs on the engine is oftentimes such that mounting and dismantling is difficult and special wrenches necessary. The spark plugs are, therefore, subject to more or less severe treatment and satisfactory mechanical strength is required.

Plugs Can Be Self-Cleaning

Some reference has been made to the self-cleaning properties above, where mentioning was made of glass as insulation body. There are two ways of obtaining satisfactory performance. One is to construct the spark plug in such a way that the insulation body is protected from oil and carbon. The other is to expose the insulation body to the heat of the explosion to such a degree that any oil and carbon that may collect on the surface will burn off. Which of the two constructions to select depends entirely on the heat-resisting qualities of the insulation body used. The two materials used most successfully at the present time are mica and porcelain. A mica spark plug must always be constructed so as to protect the mica core from heat, oil and carbon, as oil will penetrate between the layers of mica no matter how tightly these are compressed, and in time form a conductive carbon deposit.

A great variety of different constructions have been brought out, most of which have a closed bottom at the lower end of the shell with a small central hole through which the center electrode extends. For a construction of this kind special precautions must be taken to avoid preignition, as will be mentioned below. The sparks jump from the center electrode to the edges of the hole in the bottom which forms a ring-shaped electrode. This construction will cause somewhat harder starting of the engine and poor throttling ability at very low speeds due to the fact that the sparks are divided over a ring-shaped area and will separate in a number of tiny streaks rather than condense into one strong spark. The sparks are, furthermore, not exposed to the fresh gases in such a favorable way as when jumping between two pointed electrodes extended free of the shell.

A better construction is secured by providing a recess inside of the shell that will act as a baffle plate instead of closing the bottom. This baffle must be located slightly inside of the shell and the center electrode extend through it to the lower part of the shell, where a connectional ground wire electrode is used.

A few different constructions commonly used are demonstrated in Figs. 1, 2, 3, 4. The semi-circular bend of the ground wire in Fig. 1 is claimed to minimize warpage of the wire and change in the size of the spark gap when the wire becomes hot and expands. Other types of closed bottom spark plugs use a disk-shaped center electrode closing up practically all the space between the wall of

Digitized by Google

the shell, leaving only a gap of 0.02 in., which acts as the spark-plug gap. This type offers the same inherent disadvantage in starting and throttling as the type shown in Fig. 1.

With porcelain as insulator, the open-end plug has proved most successful hitherto. The quality of the various porcelains has been much improved, and it is possible to use a plug where the lower end of the porcelain extends almost to the lower end of the shell and is exposed directly to the heat of the flame. The temperature of the lower end of the porcelain becomes so high that oil and carbon are immediately burned off and the surface remains clean.

Great Strength Is Needed

It was necessary to develop porcelain compositions of great mechanical strength at high temperatures to obtain this, and, furthermore, to compound the glaze so that the expansion coefficient of both materials is practically alike. Difference in expansion coefficient will cause blistering of the glaze after a few hours run of the engine. This has especially been found where materials of the soapstone variety have been used as insulators and has prevented the further use of these materials, which in other ways offers several advantages and which has proved extremely successful for automobile practice. The closed-end porcelain plug has been used to some extent, as it offers certain advantages which will be indicated later.

All insulation materials used in spark-plug construction decrease in electrical resistance with increasing temperature. While the temperature at which this commences is far above the temperature reached in the average automobile spark plug, the temperature of the aviation engines approaches so much to the critical point of insulation material that improvement and development was necessary. A great variation in the different porcelain compositions existed and a thorough research of a large number of compositions resulted in a far better grade of porcelain being used to-day than a year ago.

Insulation Resistance Important

A material decrease in insulation resistance will cause an electrical leakage from the center electrode to the shell and result at first in a weakening of the spark which under unfavorable carburetion and distribution of the charge may cause failure in ignition. This is so much more the case with aviation engines as these are commonly of the multicylinder types, which puts a greater demand on the ignition apparatus on account of the higher speed and the greater number of sparks required. It becomes, therefore, of vital importance to preserve every atom of heat and energy in the ignition sparks.

So far, the largest amount of difficulties encountered has undoubtedly been due to breakage of the porcelain on account of heat and uneven expansion. The breakage occurs on the lower part of the porcelain which extends free inside of the shell. The causes are various. The uneven heat of the porcelain will set up internal stresses, the difference in expansion between the metal of the center electrode and the porcelain will, if too large, cause tension between these two parts sufficient to crack the unsupported porcelain; the continuous impact of the explosions and the great change in temperature when the engine is started or stopped tends to shatter the structure and to destroy the mechanical strength of the porcelain.

A breaking or chipping of the porcelain inside of the spark-plug shell is liable to cause serious damage to the engine itself, in addition to the disturbance in the performance, as porcelain pieces may be wedged in between the piston and the cylinder wall and score the latter. To avoid this, several constructions of porcelain plugs with closed bottom, similar as shown for mica plugs in Fig. 1, have been brought out. The porcelain chips will be caught by the bottom wall and prevented from entering into the cylinder. It has, however, been found rather difficult with this construction to maintain a clean porcelain and prevent fouling, although further and more satisfactory development of this design is to be hoped for.

Closed Ends Cause Preignition

As mentioned above, the closed-end plug is liable to cause preignition. This is caused by the hot gases passing up and down through the space around the center electrode into the inner chamber. In order to reduce this effect it is necessary to provide additional holes in the bottom so as to divert part of the hot gases through these holes and away from the center electrode. The center electrode is the member that causes the preignition, as it is the hardest part to cool, due to the fact that it extends through the insulation body, which also acts as a perfect heat insulator and tends to retain the heat in the electrode. The only point of the electrode that is exposed to any cooling effect is the upper end that extends above the porcelain, and this end is in many cases covered with a brass cap which the electrode merely touches lightly, a joint that has practically no value as a heat-carrying point.

The diameter of the center electrode should be as large as it is possible to use without getting into difficulties from expansion and the upper end should form a good contact with the brass cap, which in turn may be provided with cooling fins. The lower end, which extends beyond the porcelain, must be as short as possible and eventually of a smaller diameter than the rest of the electrode, so that it will collect as little heat as possible. The ground electrode is not very likely to cause preignition unless it is excessively long. The material for the center electrode should be as good a heat conductor as possible.

A good practise has been to make the lower part of nickel alloy wire and the upper part of copper. In this case precautions must be taken to see that the joint between the two wires is such as to form a good heat carrier.

Different Mica Constructions

In a mica plug two different constructions are prevalent; both are giving about the same result in service. In the first construction the mica layers are mounted horizontally as washers around the center electrode. These washers are held at the bottom by means of a flange on the electrode and at the top by a nut or by riveting a small disk to the electrode. The pressure which the nut or the disk exerts upon the mica washers must be great so as to hold them tightly together and form a compact core.

It is necessary, therefore, that the electrode possesses sufficient mechanical strength to withstand the reaction of these forces, and it must be especially borne in mind that this electrode is exposed to heat which will cause expansion and reduce the pressure upon the mica washers. A material should, therefore, be chosen which has a small coefficient of expansion, great tensile strength and good heat-conducting qualties. The electrode should, furthermore, be provided with cooling fins on the upper end to reduce the temperature throughout its length.

For the other construction of mica plugs, the mica is wound axially around the center electrode. While in this case the expansion of the center electrode has no harmful effect on the insulation core, special provisions must be made so as to protect the lower end of the mica from splitting, and the core should, furthermore, be subjected

Digitized by Google

to some sort of an impregnation that will prevent leakage taking place between the mica layers.

In order to resume the various requirements as stated above, it may be said that a satisfactory spark plug must fulfill the following conditions: All materials used for the main parts of a spark plug shall have a low coefficient of expansion. This coefficient shall not be the same for all parts but invertly proportional to their heat-conducting quality. For instance, the expansion coefficient of the center electrode shall be lower than that of the porcelain, due to the higher temperature of the electrode. In cases where it is impossible to fulfill this condition it will be necessary to make such provisions as will allow the expansion of a certain part to take place without causing any disturbing effect on other parts of the spark plug.

The center electrode must be well cooled, preferably with fins on the upper end, and only a small part of the electrode shall be exposed to the heat of the engine, *i.e.*, the extension beyond the lower end of the insulation core shall be very short and of small diameter, sufficient only to prevent warpage under heat. All points in the center electrode should be welded or of a similar construction that will insure heat conductivity. The ground electrode must be short and rigidly held, and preferably consist of a single-point electrode. The lower end of the shell must be given such a shape as will protect the insulation body from oil and carbon unless the material used is of sufficient heat-resisting quality to withstand the heat of the explosion and permit the carbon to be burned off. If cement is used this must not soften or deteriorate at temperatures somewhat above service temperature.

Scotland Favors Light Farm Tractors

(*Continued from page* 28)

of this space, but, on the other hand, many others, including the single-unit machines, were able to turn in half this space, or even less. These smaller outfits also occupied less time in turning, being in many cases able to go out, turn, and reenter without any stoppage or slackening of speed. Some of the larger outfits required a considerable amount of maneuvering before the tractor and plow could be got into position to commence the next furrow, especially when called upon to make a close turning. The furrow ends were in some cases irregular, but this may have been due to lack of proper care on the part of the driver.

Best Price

The question of price is a difficult one under the present abnormal conditions. Makers should, however, aim at putting a tractor on the market at a price not exceeding $1,500.

As at the demonstration at Stirling two years ago, it is again matter for regret that British makers of agricultural tractors were not more adequately represented. The same causes which operated against their taking fuller part then are still, unfortunately, in operation. Only about one-fourth of the machines entered were of British construction.

Demonstration Valuable

Regarding the demonstration as a whole, the committee feels that it has served a useful purpose in providing an opportunity for all interested in agriculture to form an estimate of the capabilities of the machines exhibited, and it is hoped that the effect may be to make mechanical cultivation more popular in Scotland than it has been hitherto. In this way the interests of increased food production may be served. At the same time it is obvious that such a demonstration must be of great value to manufacturers in demonstrating the points in which their machines are defective and the directions in which improvement should be sought.

The committee is glad to be able to record that the result of the demonstration has been to show that extraordinary progress has been made within the past two years, and for this advance great credit is due to agricultural engineers and manufacturers.

Condensed Tractor Specifications

BELOW is given the blank for condensed tractor specifications as adopted at the recent Minneapolis meeting of the Tractor Division, S. A. E. Standards Committee. It is intended for use in tractor catalogs.

1. Firm name and address.....
2. Tractor trade name or model number.....
3. Drawbar hp. .....
   (*Old trade rating and S. A. E. rating.*)
4. Belt hp. .....
   (*Old trade rating and S. A. E. rating.*)
5. Motor make—bore and stroke.....
6. Number of cylinders and cycle.....
7. Normal speed, r.p.m.....
8. Lubrication system or type.....
9. Ignition .....
10. Carbureter and fuel system.....
11. Cooling system, type.....
12. Belt pulley diameter, face and r.p.m.....
13. Transmission type or make.....
14. Number speeds forward.....
15. Rate m.p.h.: Low..... Plowing..... High.....
    (*At normal engine speed.*)
16. Number of wheels and arrangement.....
17. Number, diameter and face of drive wheels.....
    (*If track type give number, track, length and width.*)
18. Number, diameter and width of non-drive wheels.....
19. Frame construction .....
20. Wheelbase and tread.....
21. Total width overall.....
22. Total length overall
23. Turning radius .....
    (*One-half diameter largest track circle.*)
24. Total weight, less fuel, water, oil and lugs.....
25. Shipping weight, including standard equipment and stays .....

A New Aluminum Solder

A SOLDER for aluminum is being marketed my the Sterling Aluminum Solder Company, Inc., Brooklyn, N. Y. Repairs of broken aluminum parts by the use of this solder are said to be cheaper and quicker than repairs by other methods. One of the special advantages of the solder is that it requires only a low temperature (300-350 deg. Fahr.) to melt it, and that no flux or acids of any kind are required. It is applied with the aid of the gasoline torch. The surfaces to be soldered are first thoroughly cleaned with a steel brush; then a thin coating of the solder is applied, which is also brushed with the steel brush, and finally another coat is applied for the purpose of joining the parts. It is claimed that this solder protects the metallic aluminum against oxidation. Greater strength is claimed for the solder than that of the aluminum itself. Owing to the low temperature used in melting the solder there is no danger of warping or distorting the parts, and the aluminum will not be deteriorated by excessive heat. One of the most important automobile repairs to which this solder has been applied is that of a broken crankcase.

Truck Efficiency Graphically Shown

1—Need for Rapid Loading Not Realized
2—Short Hauls Suit Heavy Truck Service
3—Saving Minutes Adds Miles, Cuts Costs
4—Charts Eliminate Need for Calculation

By Francis W. Davis
Assistant Chief Engineer, Motor Trucks, Pierce-Arrow Motor Car Co.

THE problem of analyzing motor-truck transportation is fundamentally different from other so-called modes of transportation in that we have to do with a factor of far-reaching importance in determining the capacity or ability of motor trucks to perform a given amount of work. This factor is the so-called loading and unloading time.

At first sight, it appears to be of little importance, as when considering horse team haulage very little attention is given to it. This is quite natural when we consider the fact that a team of horses can only cover a relatively small mileage in a day, and their average speed is of sufficient magnitude to cover this limiting daily mileage in a few hours, consequently the necessity for quick loading and unloading can be almost disregarded when dealing with team haulage.

With a motor truck we are face to face with entirely changed conditions. The capacity of the truck is only limited by the number of hours it is in operation, and by operation we mean actual *running* time and not merely the time the truck is in commission.

It is true that the facts as outlined above are instinctively understood by truck operators, and more and more time and effort is put into devising ways and means for reducing the so-called loading and unloading time of motor trucks. We hear of overhead hoppers, demountable bodies, loading cranes, winches, mechanical dump bodies, and innumerable other devices for saving time. This is all done for a very definite purpose, and it is strange that up till very recently little effort has been given to the important study of the absolute necessity for reducing this loading and unloading time and showing the relative amount of work that can be produced where efficient loading and unloading appliances are considered as compared with old out-of-date horse methods.

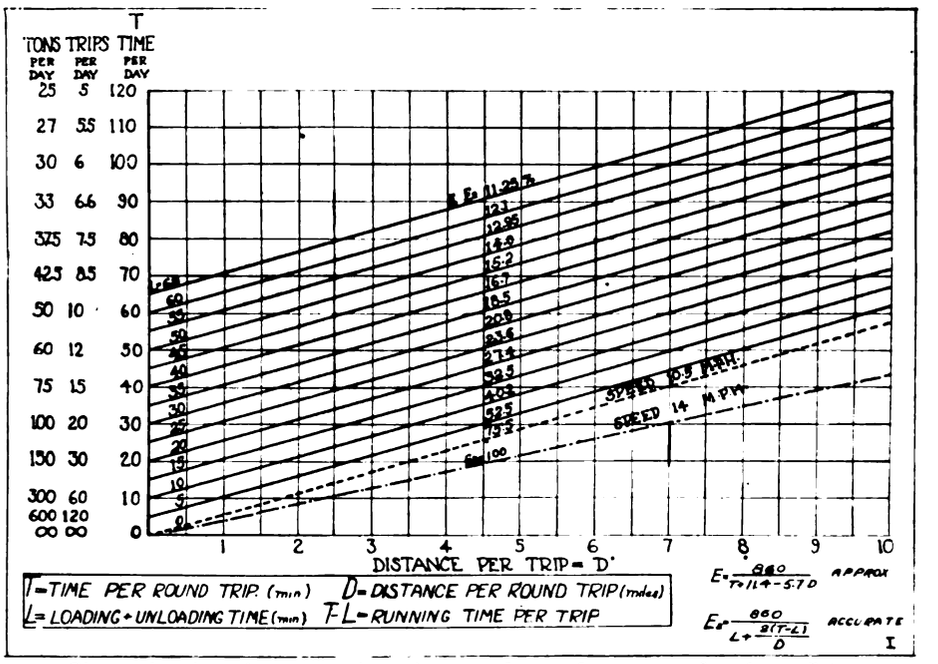
In approaching a problem to determine whether motor trucks can be used to advantage in a given transportation problem or to study means for increasing the efficiency of a motor-truck installation, it is customary to carefully investigate the loading and unloading conditions, nature, and distance of routes traveled, and other facts of more or less importance in order to draw up a report covering the capacity of a given truck under certain conditions.

In addition to this, it is also customary to investigate the problem from a cost standpoint to determine the fixed charges per day and so-called operating expense per day, the latter usually worked down to a cost-per-mile basis.

Calculating Truck's Working Capacity

In calculating the working capacity of a truck, we determine the round-trip distance of the haul, which we will call D. The loading plus the unloading time for each trip we will designate by L. Then, with an assumed ten-hour working day, the one remaining factor which we are in need of is the operating speed in miles per hour which we expect the truck to maintain during its period of operation.

Experience indicates that while a truck is in motion it averages approximately 75 per cent of the full governed



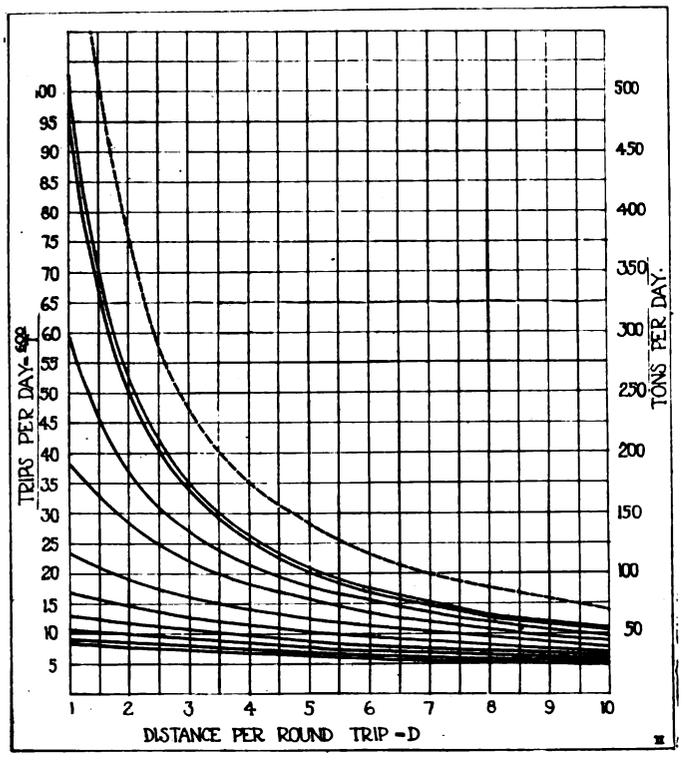


Chart showing time per trip, trips per day and tons per day for a 5-ton truck of 10.5 m.p.h. running speed, different round trip lengths and loading times.

Digitized by Google

Tons per day and trips per day for different round-trip distances

speed. The loss of 25 per cent is occasioned through traffic delays, varied road conditions, and other factors which are quite beyond control. With the 5-ton truck governed to 14 m.p.h., the 75 per cent figure amounts to an average rate of 10½ m.p.h.; therefore, while in operation we say the 5-ton truck will cover a mile in 5.7 minutes' running time.

With this information at hand, we are in position to proceed further, and in order determine the time per round trip, which we will call T, it is necessary to multiply the distance D by 5.7 and add this figure to the loading and unloading time L per trip.

To determine the number of trips per day, it is then necessary to divide 600 (the number of minutes in a day) by the time per round trip T in minutes.

The above is an extremely simple operation, and yet it is the basis for estimating truck work, and is invaluable in arriving at a working basis for considering the cost figures.

The following symbols will be of assistance in following this analysis:

D—Distance per round trip in miles.
L—Loading plus unloading time per trip in minutes.
R—Running time per round trip in minutes.
T—Total time per round trip in minutes.
M—Maximum speed in miles per hour.

75 per cent of M = running speed.

$$T = L + R$$

$$R = \frac{60\ D}{0.75\ M}$$

$$T = \left(L + \frac{60\ D}{0.75\ M}\right)$$

M = 14 m.p.h. (for Pierce-Arrow 5-ton truck)

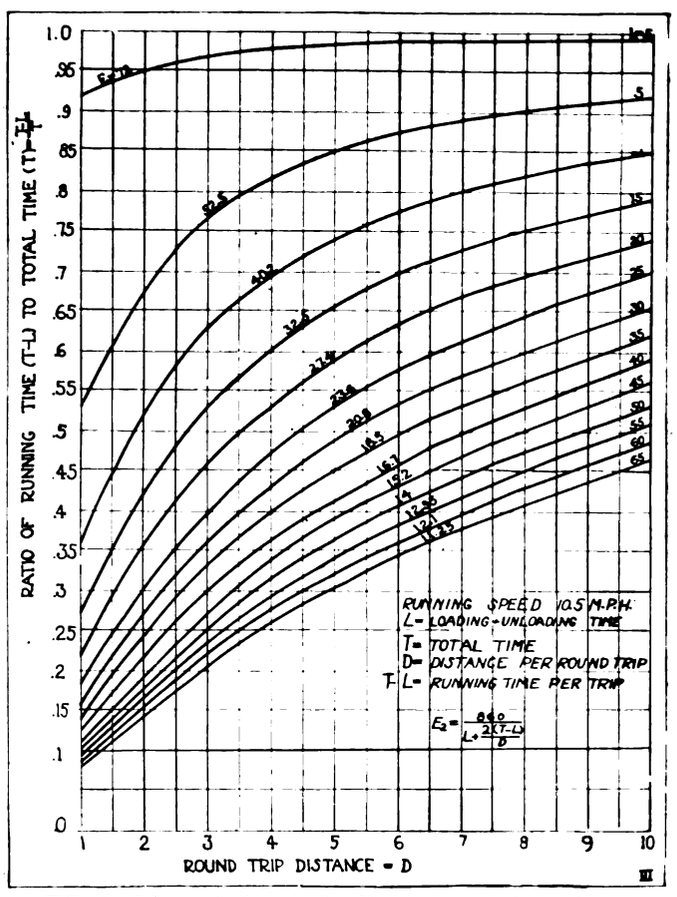
$$T = (L + 5.7\ D)$$

10-hr. working day = 600 minutes.

$$\text{Trips per day} = \frac{600}{T} = \left(\frac{600}{L + 5.7\ D}\right)$$

Truck carries out 5 tons; returns empty

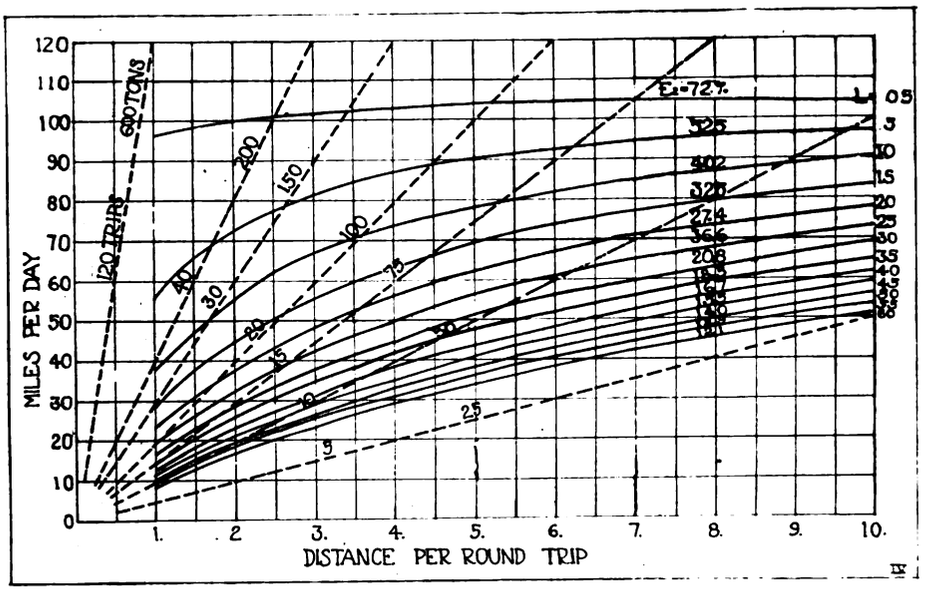
$$\text{Tons per day} = 5 \times (\text{trips per day}) = \left(\frac{3000}{L + 5.7\ D}\right)$$



$$\text{Miles per day} = D \times (\text{trips per day}) = \left(\frac{600\ D}{L + 5.7\ D}\right)$$

$$\text{Ratio running time to total time} = \frac{R}{T} = \left(\frac{T - L}{T}\right)$$

Let us carry this line of thought a little farther. The above method of figuring gives us a rapid and accurate method of determining the capacity of a motor truck under any given conditions. However, very often in discussing the usage of motor trucks with a prospective owner the item of loading and unloading time is not only difficult to estimate but often is subject to considerable revision through the consideration of some simple auxiliary equipment. The prospective owner is usually quick to raise objections against this, due to the cost of the equipment. Then the figures showing the capacity of the truck must be corrected to show its increased capacity due to the addition of this extra equipment.



This process can be repeated a number of times, and if done rapidly and accurately will give the truck owner a good idea of the increased capacity of his equipment due to quick loading and unloading.

With a view to showing this graphically, and in such a way as to admit of instantaneous comparisons, the accompanying charts, with the above facts incorporated, obviate the necessity for actually putting down figures, and permit of comparisons, one truck with another, under varying conditions. The charts also answer in a remarkable manner the old-time fallacy that motor trucks cannot compete with teams in short hauls. The short

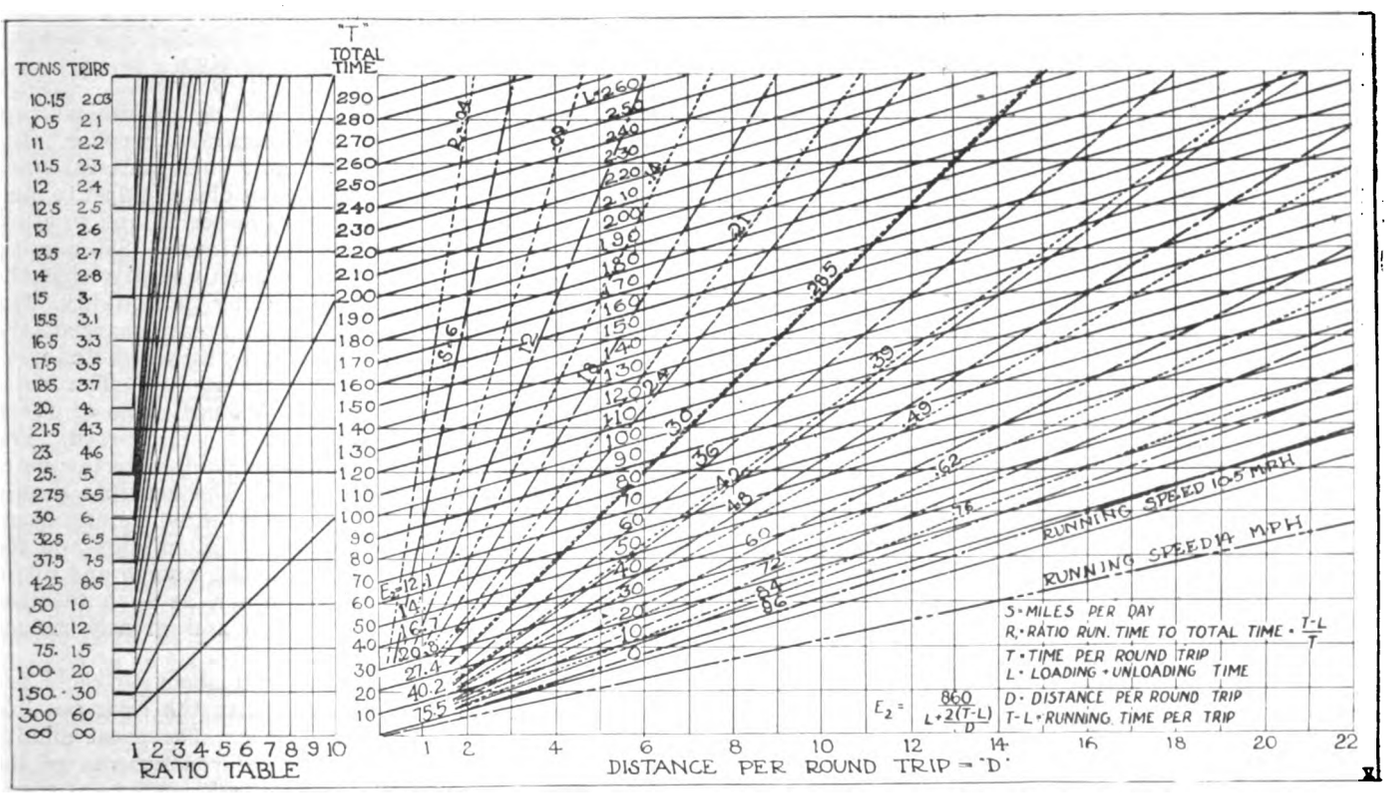
Effect of time lost in loading and unloading on daily mileage

haul is the "bonanza" of motor-truck haulage where the conditions are right.

Chart 1 is drawn up for the Pierce-Arrow 5-ton truck, on the assumed running speed of 10.5 m.p.h. The distance per round trip *D* is shown on the base line up to 10 miles. The time per round trip *T* is shown on the vertical line at the left of the chart, and runs up to 120 minutes. The loading and unloading times are indicated by *L*, and vary from zero up to 65 minutes per trip. Two other vertical scales are included, namely, the trips per day and tons per day, the tons per day bearing the relation of five times the number of trips per day, inasmuch as we are concerned with a 5-ton truck and assume a load of 5 tons carried out.

The chart is read by:



1. *Running out the base line to the distance per round trip.*
2. *Then vertically to the intersection with the L line.*
3. *Then follow horizontally to the left to the intersection with the three vertical scales, giving the time per round trip, trips per day, and the tons per day.*

By using the same distance per round trip, and dropping down to a lower *L* figure, we arrive at the time per round trip, trips per day, and tons per day with the new loading and unloading condition. This can be done rapidly, and gives surprising results when dealing with reasonably short hauls and small values for *L*.

The other figures of *E* and *E*2 represent efficiency figures which the writer has worked out at considerable length, starting from quite different grounds of reasoning, and yet the lines representing values of *L* are constant efficiency lines, and the formulæ *E* and *E*2 give equal values for truck efficiency on these lines.

Chart 2 uses the same base line as 1, with altered scale of trips per day and tons per day, so as to show the enormous increase in capacity of the truck when operating on short hauls under efficient conditions of loading and unloading, and it furnishes a graphical proof of the often repeated assertion that quick loading and unloading time is much more essential in short hauls than in long hauls.

This statement is true, and with this chart it is brought out to an astonishing degree. For instance, it shows that in a round-trip haul of one mile, with loading and unloading time *L* of 60 minutes, the 5-ton truck can make approximately nine trips per day, carrying a total of 45 tons. When reducing *L* to five minutes per round trip,

Master chart showing the relation between all factors involved in motor truck operation

Digitized by Google

the truck will make approximately sixty trips per day carrying 300 tons. This represents an increase in capacity of over 600 per cent. Further, if we consider this same haul with a loading and unloading time of ½ minute, which has been reached in certain installations, the truck has a capacity of 96 trips per day of 480 tons. This represents an increase over the first condition of approximately 1000 per cent. These are the facts that must be brought home to the truck user in order for him to get the full benefit of his equipment.

Operating Only One-Fifth of Time

How often do we hear that a truck is on the road only one-fifth of the day? This is the condition under which a great many trucks operate, and also a great many do not equal this figure. Chart 3 gives graphically a picture which shows that when a truck operates under this condition the owner should be indicted for criminal misuse of his equipment. On Chart 3 the point two-tenths of the way up on the left-hand scale—*i.e.*, representing the condition of one-fifth running time—shows that the operator in this case is operating his truck only up to this level. Above that is the region which he knows nothing about, and in which he denies the truck the opportunity of working. The limiting capacity of the truck, of course, is that it may be on the road the *entire time.* Figures of *E*2, given both on Charts 2 and 3, represent constant efficiency lines the same as on Chart 1.

There is another figure of importance, namely, the number of miles per day the truck will cover. Chart 4 is drawn up with the same base line as the other charts, and indicates the miles per day as related to the loading and unloading time, and also the relation of the trips per day and tons carried, as related to the miles per day. This chart again shows that when we reduce the loading and unloading time we increase the capacity of the truck, and on short hauls this increase goes up to an amazing figure.

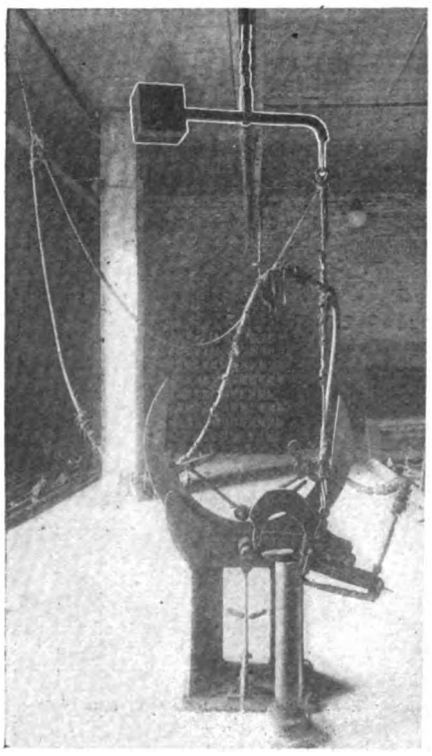


Chart 5 is a master chart of the others shown before, and includes all of the information contained on the foregoing charts. In addition, the base line is extended up to 22 miles and the time per round trip extended up to 300 minutes. The vertical scale for the total time per trip is marked T. A ratio table will be noted at the left end of the chart. This is useful where making comparisons so as to show the ratio of increase in the number of trips per day and tonnage hauled under conditions where quick loading and unloading are considered, as against one where slow loading and unloading are considered.

Determining Increase

The procedure is to locate the number of trips per day on the vertical scale corresponding to the slow-loading figure, and, by tracing out to the diagonal line, reaching down to the greater number of trips, the vertical line from that point to the ratio table indicates the ratio of increase. This is somewhat difficult to explain in wording, yet a short study of the chart will show how easily and quickly it can be done.

The foregoing charts should prove not only of great value in analyzing new transportation problems, but should place in the hands of traffic managers means whereby trucks can be distributed for a given day's work so as to utilize the transportation equipment to the best possible advantage.

Guards for Riveting Frames

Weight used to counterbalance riveting hammers mounted on a standard Palmer-Bee track and trolley

AIR riveters used for riveting frames in automobile shops are often suspended on trolleys or cables, with a counterweight to balance the riveter. The Reo Motor Car Co. had many of the weights become detached and drop down, and this trouble was overcome by putting a yoke on the trolley with a balance weight on one end and only running a cable down. If that breaks the only thing that can come down is the hammer.

In the Packard shops use is made of a stand constructed of pipe fittings. It is adjustable for height and can be clamped into position. This stand has given fairly satisfactory results. One of the men at the Packard plant is working on a drum with a spring control so that when the hose is moved away from the connection it is automatically released. This was found to be the only solution of the problem of getting around the truck frames to rivet them together.

Melting Aluminum Scrap

THE fluxes commonly used in melting aluminum scrap, says *Brass World,* are fluorspar, cryolite, and salt. An excellent way of utilizing such material when a part of the scrap is small and not clean is first to melt a bath of aluminium, using solid material, and to allow it to reach a temperature of approximately 850 deg. C., then add the sweepings, etc., in such quantity that the bath will absorb them without losing its liquidity. The bath is then reheated and more scrap charged, the process of charging and reheating being alternated until the crucible is as full of metal as desired. The metal will most likely be pasty, and a small piece of fused zinc chloride is added and the bath well stirred. The resulting action will free the mixed oxides and the metal will assume its natural fluidity. The crucible should be immediately emptied of aluminium before any reaction can occur between the metallic aluminium and the heated oxide on the one hand and the oxygen and nitrogen of the atmosphere on the other, as such reaction will consume metallic aluminium and greatly reduce the percentage recovered.

Now that aluminum is quoted at about 60 cents per pound the recovery of all scrap with the least possible loss has assumed great importance. The great affinity of the molten metal for the chief constituents of the atmosphere renders the process difficult.

Probable Advances in Motorcycle Design

New Types of Engines That May Come to the Front—Simplification of Equipment —Changes in Frame Construction Likely

IF the next few years should see a great increase in the demand for motorcycles, as is confidently expected, we may hope to see also a great deal of improvement in design, partly to render the machine more serviceable as a conveyance and partly to facilitate its production on a large scale—in other words, to make it a better manufacturing proposition. It is true that the present standard makes of motorcycles are very serviceable machines, but not even the designers themselves would contend that the zenith in engineering development has been approached within measurable distance. A widening market naturally encourages development work, for the greater the prize the greater the stakes that capitalists and engineers are willing to put up.

In regard to engines the situation in the motorcycle field is at present somewhat unsettled. Engines from one to four cylinders are used, though the two cylinder Vee type is distinctly in the lead. The selection of this type must be regarded as a compromise. Having two cylinders it is somewhat smoother running than a single cylinder, and it obviates some of the complication of the four cylinder. What undoubtedly decided the question in favor of this type of engine is the fact that it fits well into the conventional frame. Since the angle of Vee is always considerably less than 90 deg. the engine is not well balanced, and, besides, its explosions are unequally spaced.

From the standpoints of balance and uniform spacing of impulses the best type of engine with only two cylinders is undoubtedly the horizontal opposed type. This engine was successfully used for automobile work for many years. The objection to it is that it is of unwieldy length and very difficult to accommodate on a car. This objection might seem even more potent on a motorcycle, but practically it does not work out that way. The motorcycle industry probably has seen a greater development in England than in any other country and one of the best known English motorcycles, the Douglas, has a double opposed engine.

What may be called the displacement efficiency of the motorcycle engine has been increased to such a degree that for a light machine an engine of very small piston displacement now suffices. On the heavier machines the piston displacement is always between 60 and 61 cu. in., that is, just inside the limit set for racing machines. But for ordinary service over moderately good roads an engine with between 35 and 40 cu. in. piston displacement should deliver all the power required. To keep the length of the engine within bounds a comparatively short stroke would be chosen, say very slightly greater than the bore. A bore of 2¾ in. with a stroke of 3 in., for instance, gives a piston displacement of about 36 cu. in. Such an engine can be built not to exceed 22 in. in length over all, and if the connecting rods are made short and the wristpins located as close to the top end of the pistons as possible—practices which do not conduce to long life of the engine—even this length can be materially cut. There is no difficulty in placing such an engine between the two wheels.

Light weight is certainly a desirable feature, and if it is advantageous to cast the cylinders of large touring cars of aluminum, the same practice applied to motorcycle engines should yield good results. There should be no need for liners of cast iron in an aluminum cylinder of this small size, for it stands to reason that if an aluminum piston in a cast iron cylinder has a satisfactory life, an aluminum cylinder having a cast iron piston working in it should leave little to be desired. In fact, the combination should be almost ideal because the lower coefficient of expansion of the cast iron would be compensated for by the higher temperature of the piston, so that a very slight clearance on the piston would suffice and the piston would be substantially the same fit in the cylinder whether the engine were hot or cold.

Minor advantages of the horizontal opposed engine are that it lowers the center of gravity of the whole machine, rendering it safer, and that it tends to equalize the cooling of the two cylinders.

Certainly one of the least satisfactory features of the present day motorcycle is the free chain drive. As long as the chain is clean and well lubricated it gives good service, but it is impossible to keep it so in regular service. When dirt accumulates upon the chain it soon gets into the numerous pin joints and the chain becomes squeaky, wears and "stretches." On the average motorcycle there is not only one chain for the final drive, but an additional chain for transmitting the engine power to the transmission. Some day no doubt we shall have a fully enclosed and effectively lubricated final drive on motorcycles, the same as we have on automobiles, but just how this is to be accomplished it is not so easy to say—whether by the elimination of the chain or by its enclosure. The problem of a satisfactory chain case is admittedly a very difficult one; if it were not, we should have had more motor trucks fitted with them. Of course, in a motorcycle there is no variation of sprocket centers.

Frames are at present invariably of tubular construction. The tubular section is very good from the standpoint of strength for a given weight. There are two inconveniences connected with the tubular frame, however, which may possibly induce motorcycle engineers some time in the future to follow the lead of automobile engineers and adopt pressed steel frames. The first is that tubular frames must be joined up by brazing, and the high heat required in this process tends to impair the quality of the steel in the tubes and in any case makes heat treatment of the frame impossible. The second inconvenience is that it is difficult to secure anything directly to the frame without the use of rather heavy brackets. From a tubular to a pressed steel frame would, of course, be a very radical change and would involve a complete redesign of the motorcycle.

There is a well founded impression that motorcycles are at present cluttered up with too many fitments that are not strictly necessary. A commendable step looking toward the simplification of the machines was made when, at a meeting of representative manufacturers, it was recommended to the Government that emergency brakes be left off the machines for the army.

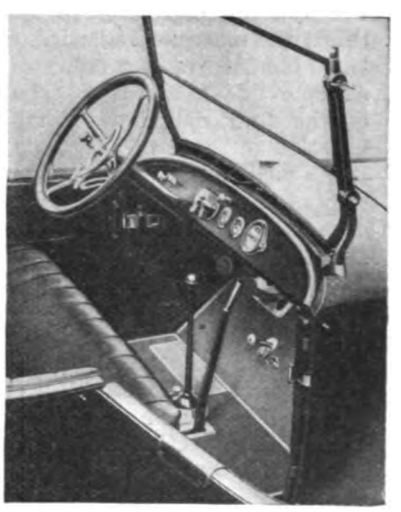
Studebaker Has an Entirely New Line

Two Sixes and a Four, with Engines of High Speed Type —Transmissions Separate and Located Amidships— Hotchkiss Drive and Fabric Universals Among Features

THREE entirely new cars will be marketed by the Studebaker Corp. for 1918. This marks an entire revision of the Studebaker line which consisted of two cars last year. The new cars are a large six on a 126-in. wheelbase, a smaller six on a 119-in. wheelbase and a four having a 112-in. wheelbase. On the larger six there is a seven-passenger touring body; on the smaller six a six-passenger, a four-passenger and a two-passenger body are offered, and on the four a five-passenger and a two-passenger.

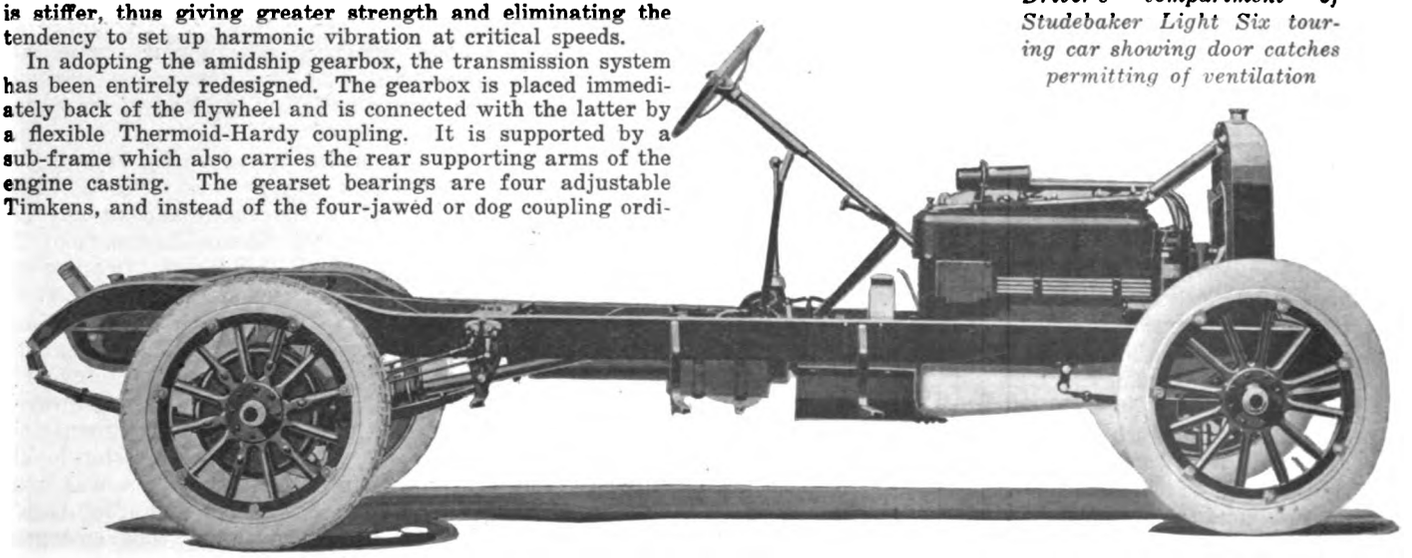
The entire line is replete with engineering features new in Studebaker practice. Probably the most significant change is the abandonment of the rear axle gearbox which has distinguished the Studebaker line for some years. This has been replaced by an amidship type solidly mounted upon the frame, with a consequent important reduction in the unsprung weight. The engines are entirely new but do not incorporate any radical features. They are all L-head engines with block cylinders, the larger six having 3⅞ by 5-in. cylinders and the smaller six and four 3½ by 5 in. The respective horsepower ratings of the three types are 60, 50 and 35. The small six and four conform to each other quite closely and are solid head types, while on the larger six the cylinder heads are removable.

The 1918 cars being new throughout contain all the engineering features which have proved their merits during the past few years and are naturally thoroughly up-to-date. The hot spot intake with the corresponding type of manifolds is included in the design.



The oiling systems have been revised in detail to give the improved lubrication necessary with high speed engines. The engines are better from an upkeep standpoint owing to greater accessibility resulting from detail features in design. For instance, a change in the fan hub and bracket makes possible the removal of the fan without disturbing the radiator. The new oil level indicator can be readily read at night. A new oil throw ring has been added to the rear end of the crankshaft to prevent leakage through the main bearing. Careful study has been given to the question of external vibration due to loose parts and improper flange connections. The result is that in the new design the flanges on the lower half of the crankcase are much wider. The crankcase itself is stiffer, thus giving greater strength and eliminating the tendency to set up harmonic vibration at critical speeds.

In adopting the amidship gearbox, the transmission system has been entirely redesigned. The gearbox is placed immediately back of the flywheel and is connected with the latter by a flexible Thermoid-Hardy coupling. It is supported by a sub-frame which also carries the rear supporting arms of the engine casting. The gearset bearings are four adjustable Timkens, and instead of the four-jawed or dog coupling ordinarily used, the second speed gear is cut with internal teeth which act as a clutch member engaging with the main pinion when in high gear. There is a new clutch brake also, which tends to facilitate gear shifting. Two Spicer universals are now used in the propeller shaft, which by the use of the amidship gearbox has been considerably shortened, thus lessening the tendency to vibrate. The intermediate section of the shaft is tubular and is butt-welded to the joints at either end.



Studebaker is now using an aluminum clutch in place of the pressed steel one of former models. Advantages claimed for this type are lightness and a truer surface, thus giving the clutch leather a better seat. Between the flywheel and the flange couplings is a clutch-release mechanism which is designed with an equalizer which centers the effort when the clutch pedal is pressed, thus pulling the clutch directly back of the spline shaft and preventing it from binding.

Frames are made of heavy carbon steel stock. The four-cylinder model has a frame section of 4½ by 1¾ by 5/32 in., the Light Six cylinder model, 5 by 1¾ by 5/32 in. and the Big Six 5½ by 1¾ by 5/32 in. The new shape of frame which follows the lines of the body is of advantage since it gives a short turning radius, saves weight and gives the motor a better and closer support. In the new chassis designs exceptionally high factors of safety have been used in the frame and every other important part.

The rear kickup of the frame sidebars is sufficient to allow ample jounce space.

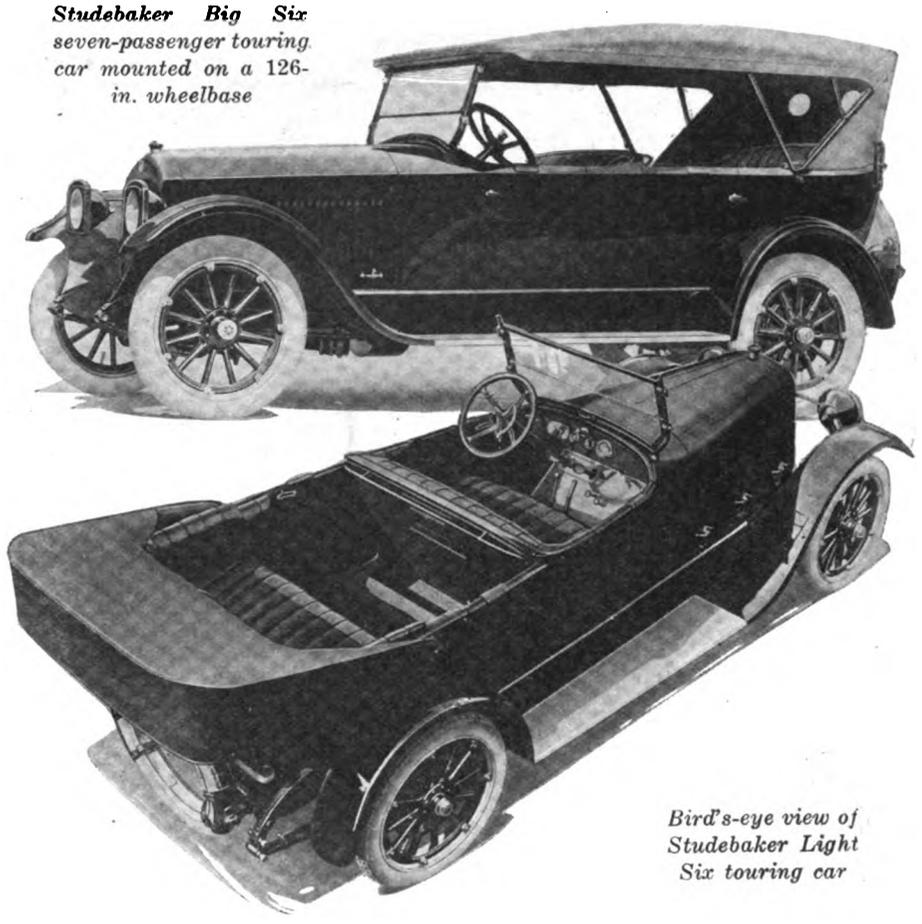
Digitized by Google



Five cross members and a cross tube connect the sidebars and distribute the load very nearly uniformly. The wide cross member near the rear is of channel section and is well gusseted to the sidebars to resist frame weave. Below this cross member are carried the brake cross shafts with equalizer. These shafts are bracketed to the sidebars, and all of their bearings are lined with oilless bushings. The rear portion of the frame sidebars follows the line of the body sills, and greatly stiffens them.

Two channels run lengthwise of the frame between the sidebars. They are secured at one end to the motor support brackets, the other end resting on center cross brackets. This sub-frame construction serves to carry the transmission case and the pedal shaft brackets.

The Hotchkiss drive is now used, in connection with semi-elliptic springs underslung at the rear. These are of chrome vanadium steel and have the spring eyes bushed with bronze. The bushings are claimed to be true to 1/1000 in. The front axle is drop forged from high carbon steel. The steering knuckle has two Timken bearings for each front wheel, and the knuckle pin, instead of being secured to the axle, is now secured to the knuckle and rotates in hardened and ground bushings pressed into the axle jaws. This design permits of a greater span between the bearings.

Another new feature of the chassis is that in place of the continuous dust pan beneath the engine there is a sectional pan fitting between the frame side bars and the crankcase. This results in greater accessibility of the motor oil pan and greater road clearance at this point.

Studebaker Big Six seven-passenger touring car mounted on a 126-in. wheelbase

Bird's-eye view of Studebaker Light Six touring car

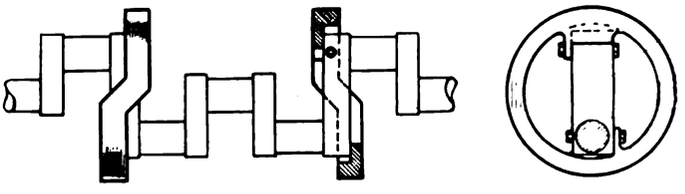
The generator has been improved by the use of a pressed steel housing and is lighter and smaller than the former type. In other details the electrical equipment is the same.

The lighting switch provides two degrees of dimming, and on the Big Six there are silver dials on all registering devices. The battery terminals have been so designed as to fit practically any make of battery, as a convenience for the owner. The standard type furnished is the 100 amp.-hr. Willard. This is used in connection with a Remy ignition system which has been improved by the use of a waterproof distributer cap.

It is in the body line that the most distinctive changes have been made. The bodies are of low hung types with unbroken lines from radiator to the rear of the tonneau. They have the somewhat angular lines which have become popular in the last few months, and give a remarkably smooth and graceful appearance. In the new models all the doors swing from the rear, and the front doors are provided with catches permitting them to be held open for ventilating purposes. The front seats are continuous, providing increased body strength, and the seat backs are designed to give an improved double cowl effect. Increased room is provided in the forward compartment and there is also more room between the steering wheel and the back of the seat. The tonneau of the seven-passenger model is 2 in. longer than the old model. The slanting type of windshield has been adopted and the shroud and radiator are designed without recesses for the hood.

The Big Six is furnished regularly in options of Brewster green or Purple Lake maroon; the Light Six is dark blue and Purple Lake maroon, and the Four in black enamel. All are completely equipped with Warner speedometer, oil pressure gage, ammeter, gas and air carbureter controls, speedometer dial and dash lamp and Yale switch locks. The headlights are fitted with special diffusing lenses. The Big Six has also a Warner clock. In the rear compartment there is a combination robe and hand rail and the Big Six has a tonneau lamp with an extension cord to reach any part of the car. The foot rails on all three cars are 3½ in. wide and are covered over in limousine style.

The tire size is 33 x 4½ on the Big Six, 32 x 4 on the Little Six, 32 x 3½ on the Four.



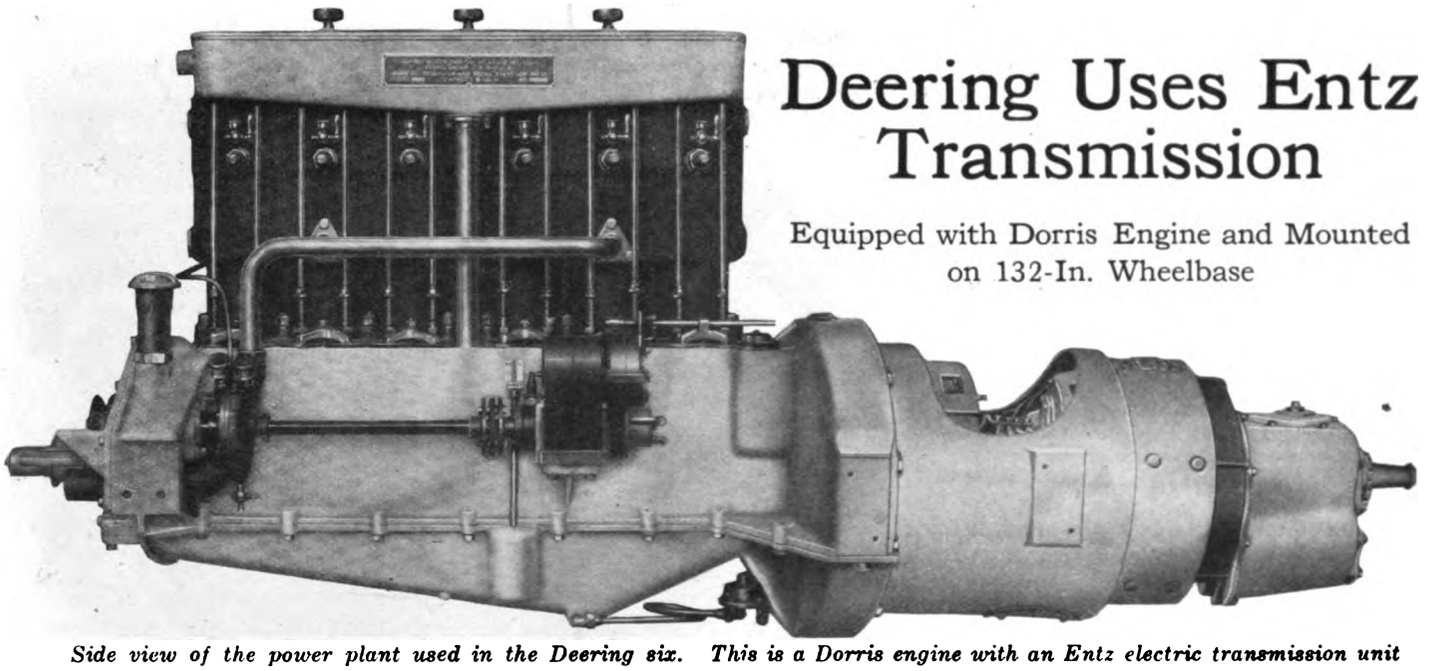
Prices of the new models are $895 for the Four; $1,295 for the Light Six; and $1,695 for the Big Six.

—

New Crank Balance System

THE system of crankshaft balancing which is claimed to be much cheaper than the majority of other forms is the invention of Joseph W. Ridgway. Briefly Ridgway's idea is to attach to a conventional crankshaft rings either of cast iron or steel, the upper and lower halves of the rings being offset. The rings can be easily attached to the shaft and being, of course, produced under rotation and coupled creating a bending moment on the shaft.

The rings are so proportioned and so arranged on the shaft that the bending moment created is equal and opposite to the moment due to the crankshaft pins and webs. This method of balancing is particularly easy of application to a four-cylinder crankshaft and will be found on the Crow-Elkhart cars in the New York show.



Ridgway crankshaft balancing system

Deering Uses Entz Transmission

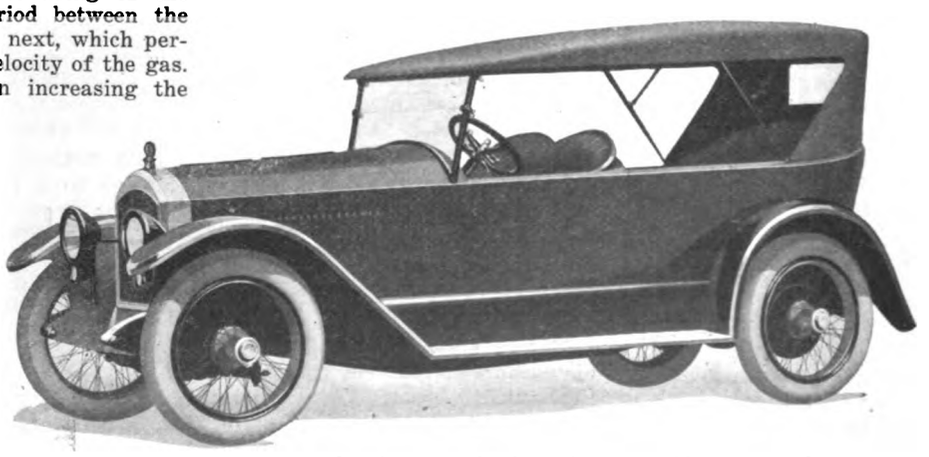
Equipped with Dorris Engine and Mounted on 132-In. Wheelbase

Side view of the power plant used in the Deering six. This is a Dorris engine with an Entz electric transmission unit

THE Deering Magnetic car, produced by the Magnetic Motors Corp., Chicago, will have the Entz electric transmission and the Dorris engine. The car is built on a wheelbase of 132 in., and in its other features follows the lines of up-to-date practice. The Dorris engine is a six-cylinder valve-in-head type with the cylinders in threes and dimensions of 4 x 5 in.

As has been explained in these columns previously, the Entz transmission eliminates and performs the functions of the electric starter, flywheel, clutch and gearbox. The engine is operated in the customary manner, but is started by the use of a small lever located on the steering wheel. This lever serves also as a speed control and operates the electric brake.

The Dorris engine has the rocker arms enclosed in an aluminum case with a removable top. This top can be taken off by turning two knurled screws and the housing also contains the upper water pipe, which takes the cooling liquid directly from the jackets above the exhaust ports. The purpose of the housing is chiefly as a dust cover for the rocker arms and valves and it also serves to keep the engine clean.



One of the features of the engine is the layout of the firing, so that the first and second sets of three cylinders operate alternately, thus eliminating back pressure and giving a smooth and continuous flow of gases from the carbureter through the two short manifolds to each set of cylinders with the avoidance of any reversal of gas flow. There is a sort of injector action set up in this way which tends to reduce back pressure rather than increase it. On the intake a ramming effect is created by the alternate firing of the two blocks of three due to the short period between the closing of one inlet and the opening of the next, which permits a pressure head to be formed by the velocity of the gas. This is an aid in filling and a factor in increasing the volumetric efficiency.

This layout of the manifolds is one of the chief features of the Dorris engine. It has resulted in a higher output from the engine both because of the better filling on the intake and from the decreased resistance to exhaust. The latter factor has been accentuated by partitioning the exhaust of the first three cylinders from that of the second three cylinders. This partition in the exhaust pipe also prevents any chance of the exhaust from the first three cylinders blowing back and refilling the exhausted cylinder of the second set. With the alternate firing, as explained, this would be the case if no partition were used, as the exhaust valves would then overlap each other to such an extent that when one valve was approaching the closing point another cylinder would open up and refill the first.

Pressure feed lubrication is used with a gear type of pump and an oil gage mounted on the side of the crankcase. Ignition is by Bosch magneto, while lighting and starting is provided by the Entz electric transmission unit. The rear axle is a floating Timken, with the Timken bearings at differential and wheels. The final drive is spiral bevel.

Bearings are used on each side of every crankpin, the purpose of this being to provide a crankshaft in which whip and vibration are eliminated. The main bearings are bronze backed and are lined with nickel babbitt. The camshaft bearings are unique in that seven of them are employed, so that there is a pair of cams operating between two bearings throughout the entire length of the shaft. This is of value not only to prevent vibration, but also in synchronizing the valve timing and to nullify the effects of springing or whipping of the camshaft. This is considered one of the points of the engine which will increase its life.

The Deering car is upholstered in black leather and the equipment includes a top and dust cover, rain-vision windshield with ventilating features at top and bottom, a 60-mile Warner speedometer with season and adjustable trip register, special tire carriers in rear, five Rudge-Whitworth wire wheels with 33 x 5 cord tires, two 10-in. headlights with double bulbs and dimmer, electric tail light and license carrier, electric horn, electric inspection light, robe rail, footrest, set of tools, jack and repair tire outfit.

Salon Exhibits Show Individuality

Cabriolets and Landaulets Predominate—Marked Improvement in Collapsible Features

NEW YORK, Jan. 2—The fourteenth annual automobile salon which is now running at the Hotel Astor lives up to its traditions of striking the dominant note in fashionable custom body work. The salon is always a body show, and in spite of war-time conditions is again displaying examples which are typical of the finest of the coachmaker's art. Because of the European upheaval the salon this year is the only automobile exhibition of international character to be held anywhere in the world.

While originally limited to motor cars of European design, the salon is now open to the products of American makers, and it is upon the American chassis that some of the finest examples of body design are exhibited. As usual, the exhibition this year typifies the fashions in custom body work and affords a prediction for what will come in a modified way in stock body design.

To a student of body design there are several facts which stand out as typifying the lesson of the salon: the improvement and adaptation of the convertible and collapsible types; the falling off in the divided front seat for touring cars; the practice of building the car body to fit the user; the increasing convenience in the control members; the better mounting of external fittings such as windshields, tire carriers, runningboards, trunk racks, etc.; the tendency toward straight line construction in both open and closed cars, and the more artistic simplicity of body interiors may all be taken as indicative of the features brought out at the Astor exhibit.

Cabriolets and landaulets predominate in the closed car exhibits at the salon. The ingenuity and fine workmanship in taking care of the collapsible features of these cars is somewhat offset by lines which are not as graceful as they should be, due to the exaggeration of the flat top. The flat roof on the closed car tends to give the appearance of an outward flare at the top, with the result that a box-like appearance can hardly be avoided.

Another weak point is in the use of horizontal bonnet lines with the short cowl, which tends to give a sagging effect at the forward end of the front compartment. This is quite noticeable on some of the town cars. The effect is avoided by others in the use of a slanting line at the side of the hood.

There are only two open cars with divided front seats at the show. The consensus of opinion among body makers is that this type is disappearing in favor of the center cowl arrangement. Where the center cowls are used they are larger and more distinct than formerly. There is no doubt a structural reason for the abandonment of the divided front seat in that it cuts an important transverse supporting member of the body. With the center cowl arrangement this transverse member is substantially reinforced with the result that it is much easier to maintain door tightness.

Some of the bodies shown illustrate the tendency to build the car to fit the needs of the user. The dimensions of the seats and the positions of the control members are arranged in these cars to suit the physical makeup of the buyer. Naturally cars of this type are the open design where the owner is to do his own driving. One of the cars which may be mentioned as an example of the built-to-fit type is a four-passenger Murray job all in aluminum. The running boards and body and hood lines are all angular, giving a sort of cubist effect. The driver's seat in this has been laid out to measurements to suit the purchaser of the car, who happens to be the son of Andrew Carnegie.

Another tailor-made body is shown at the Brewster booth where there is a sedan built for the personal use of the president of the Brewster company. This is a square type with the flat roof but in this case the flat roof has been relieved by the sloping front line of the body so that the eye is led gradually off the top of the car instead of being somewhat shocked by the abruptness generally given with a combination of flat side lines and flat top. Even the slit in the windshield is correctly placed in this car so that it will not interfere with the vision of the particular driver who will use the car.

Body attachments and other parts of the structure which must be added to the exterior are now fastened or built in with the greatest amount of rigidity possible. Where two bolts were thought to suffice for windshield supporting members three and four bolts of larger size are employed. Fender supports are universally more substantial as are also headlight brackets and fittings universally.

In the way of new products there is very little to be found at the salon. The Biddle company has its new Duesenberg engine-equipped car on the floor and a new company known as the Mercury exhibited for the first time. The new Biddle, selling for $3,650, is very much the same as the previous type on the same 122-in. wheelbase. The former Biddle is also continued selling for $2,650 with a Buda engine. No material changes have been made in the chassis except that the drive members have been strengthened to take the greater output of the Duesenberg engine.

The Mercury cars made by Mercury Cars, Inc., Hollis, L. I., have open models priced from $2,750 to $2,950 and closed models at $3,600 to $3,900. The body work is custom style exclusively. The car exhibited is a four-passenger job and is one of the two divided front seat open types on the floor. It has the angular side lines which are popular this season.

White, Locomobile and Simplex, passenger car manufacturers of long standing, showed complete lines of bodies which are more accurately of a stock nature than the other cars on the floor. Nearly all the other exhibits represent the individual efforts of custom body designers.

White shows a coupe in dark and light gray finish with cloverleaf seating which is an example of compactness in this style. The use of the two shades tends to break up the appearance of flatness which would otherwise be likely to be apparent due to the ample head room and flat roof.

Fageol, which has discontinued the manufacture of passenger cars owing to government appropriation of the Hall-Scott engine plant, shows the last of twenty-five of these cars which were put through production. The chassis alone sells for $10,000 and the entire car for $13,000. This car is geared 1½ to 1 and 750 revolutions of the motor represents a mile of travel.

Phianna has two town cars on exhibit both of which show a tendency toward narrow lines in bodies of this kind. Cunningham, Lancia, Murray and Rolls-Royce all show town and convertible town bodies which are typical of the high narrow design which seems to be nearly universal for the formal type of city vehicle.

One of the features of the show is the rectangular lined Brewster-Knight sedan which is finished in gray with red running gear. This car is a good example of light weight body design, the body itself weighing but 785 lb., or about 400 lb. less than the average Brewster-Knight sedan body. It has four doors and is finished in cane and spruce. The inside of the doors are lined with the caning material and this does away with the usual interior panel. The result is the exceptionally light weight as noted. This car is covered with a brown canvas top which extends forward so that it forms a peak for the windshield. The windshield itself has an angle formed by a horizontal projecting line and the shield does not rise and fall in the usual manner but is raised and lowered through a space of several inches by means of a lever control.

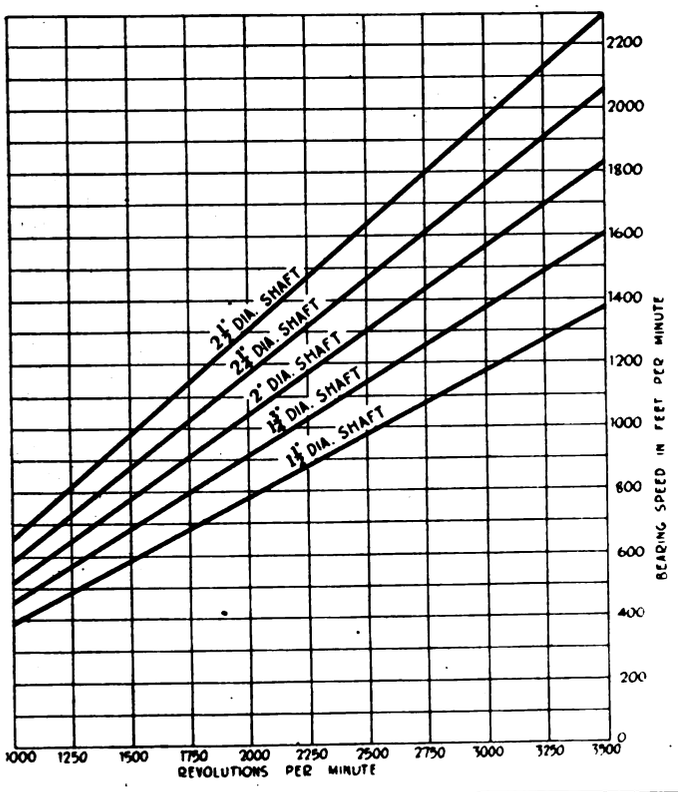
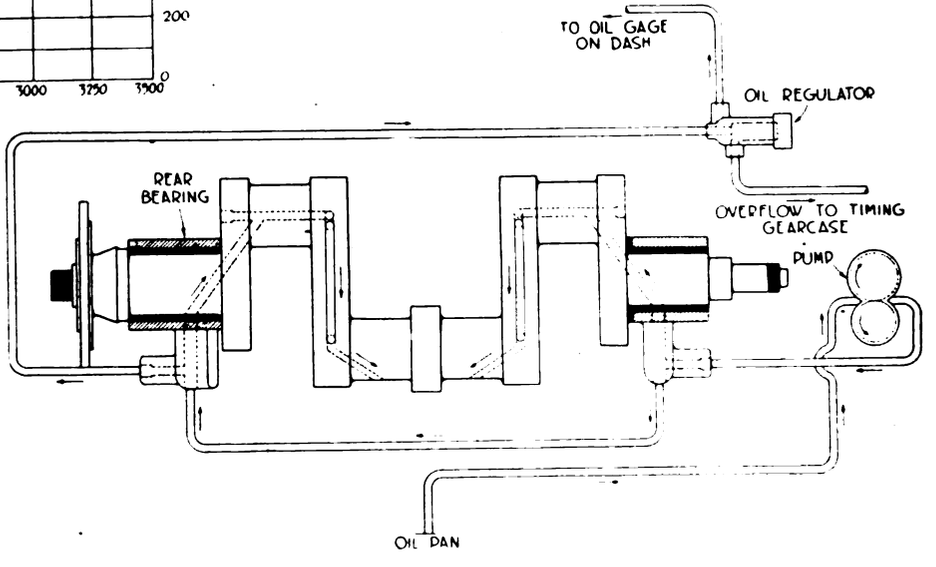
Further Increase in Pressure Feed May Result from Shortage of Alloy Steel

Bearing Speed Increasing Because of Engine Characteristics and Larger Shaft Diameter

OWING to the continual tendency toward stiffening crankshafts, there is an increase in pressure feed systems. This is natural because engine speeds, as well as crankshaft diameters, have increased, thereby giving a higher linear speed to the bearing. When bearing speeds go above 1000 ft. per min. linear velocity, the matter of maintaining the oil film becomes of the highest importance if the bearing is not to be destroyed. Even the highest quality of bearing materials will disintegrate quickly unless metal-to-metal contact is prevented. For this reason the utilization of a pressure feed is necessary.



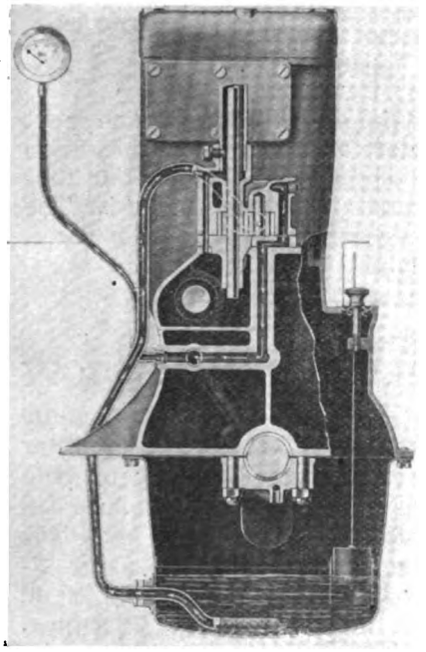
There is a tendency for the molecules of the bearing metal to be pulled out by the revolving shaft, and it is this frictional pull rather than abrasive wear which causes the destruction of the bearing.



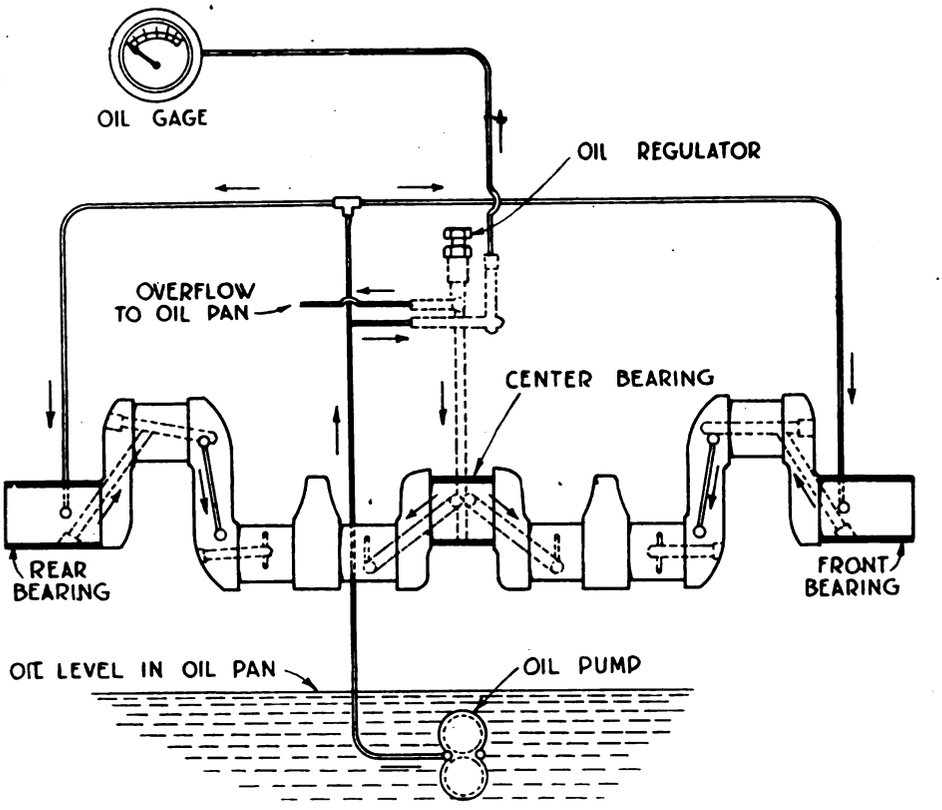
Working pressures for oil systems range from 2 to 60 lb., depending on the speed at which the engine rotates, the method of oil feed, and largely on the personal beliefs of the engineer designing the system. There are two distinct functions of the oil in reaching the main crankshaft bearings, one being to lubricate the surface by maintaining an anti-frictional film between the surfaces of the bearing and the shaft, and, secondly, a cooling function in which the flow of the oil is made use of to carry off the heat generated by friction.

Systems using the oil as a lubricant as well as a lubricating medium, and which operate with a working pressure of approximately 40 lb. per sq. in., are particularly well adapted for high-speed engines. A system of this kind generally employs a crankshaft drilled so the oil is conducted directly to all the crankshaft bearings and to the lower connecting-rod bearings. It is also quite customary to include the camshaft in the circulating system, so that the camshaft bearings as well as the cams themselves are always working in a flood of oil.

Large Strainer Necessary



One of the points which must be carefully watched in a system of this kind is that the brass wire gauze strainer is of a sufficiently large area to give the right amount of strainer space for a system which requires as much oil flow as this does. Should a small part of the area of the strainer be clogged when the strainer is only just sufficient to allow the passage of the proper amount of oil,

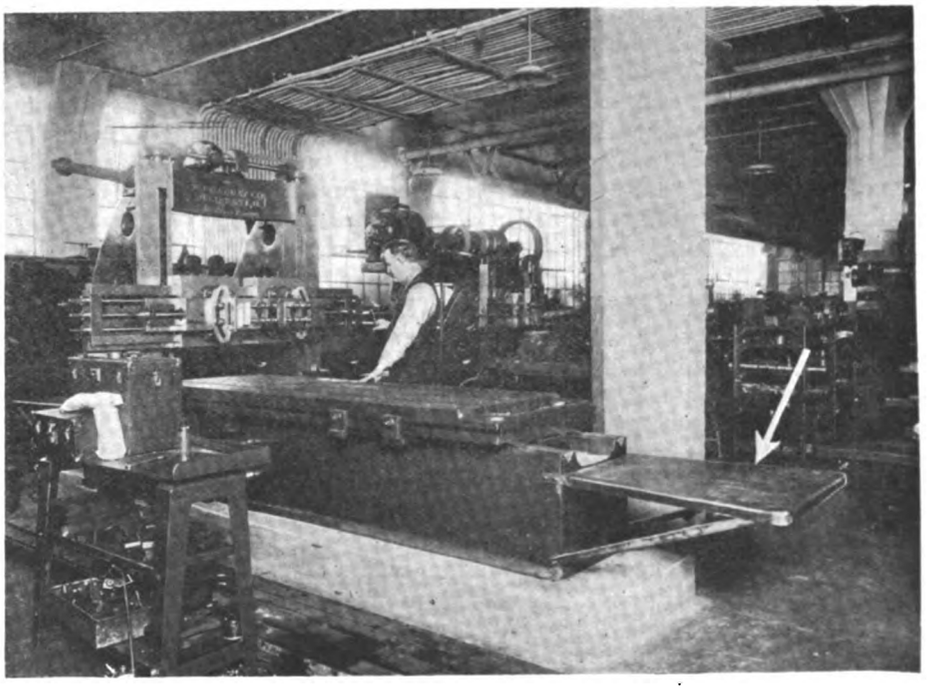


Above — Curves illustrating linear speeds of main bearings for different diameter shafts between 1000 and 3000 r.p.m. Right—Oiling diagram of the Oldsmobile 44 showing arrangements of leads and direction of flow

Digitized by Google

Above—Diagram of the Hupp pressure feed, showing self-priming pump and oil leads. Right—Layout of the Oakland-Northway oiling system, showing the path of oil and method of pressure adjustment

the result would be that the oil would back up to such an extent that the pump feed may be starved, while the interior of the engine itself may be flooded so the rods will dip, causing an undesirable splash action and consequently allowing the engine to smoke.



For the sake of appearance and cleanliness, it is advisable that the oil system be self-contained, with the exception of the pressure gage on the instrument board.

With conditions making it desirable to economize in alloy steels, it may be necessary to use carbon steel shafts of larger diameter. This will naturally give an increase in bearing speed, as shown in the curves herewith, and it may be that designers, changing to the larger diameter shaft, will have to alter the oiling system either by a change from splash over to pressure or by an increase in pressure, since it is quite customary to have the main bearings under pressure even though the remainder of the engine is oiled by splash.

Two typical pressure-feed layouts as used in passenger-car practice are shown herewith. The Oldsmobile Model 44 and the Oakland six are the two shown. On the Oldsmobile the pressure used on the system is not over 20 lb. maximum and 2 lb. minimum, while on the Oakland the pressure is arranged somewhat lower, so that at 20 m.p.h. the working pressure is from 10 to 15 lb. The pressure is set on the Oakland model by the adjustment shown in the drawing, controlling an overflow by-pass to the oil pan.

A Planer Safety Appliance

The cut opposite illustrates a safety device used in the plant of the Ford Motor Company. It is a planer extension, put onto the bed of a large planer, and prevents persons walking past the machine through the aisle from being struck by the planer table

War Show Spirit

THE big manufacturer who dropped the remark at the Detroit Athletic Club that he would not attend the automobile show this year because, to use his exact words, "It is all right to go there in normal times to play, but these are busy times," has not the best war attitude toward the coming shows.

The situation is entirely reversed; in normal times it may be all right to stay away, but under present conditions every automobile manufacturer can perform a desirable function at the show.

Dealers come to the show by hundreds in normal times, and this year they are coming in as great numbers as ever; they are coming to learn of the future business outlook. Under these circumstances the manufacturer can scarcely afford to stay away.

Now is the time when the dealer needs the national analysis that comes from talks with the best minds in manufacturing organizations. These men should be on hand and should be there every minute. The dealers need more courage. Courage is bred of a correct analysis of business fundamentals. This has been evidenced during the past 6 months, and the opportunity afforded by the show should be taken advantage of.

The show this year is not to be taken in the light of an Oriental bazaar nor a carnival to bolster up the prospect list. It is an essential business get-together.

The industry is on trial and the jury which must be convinced is the dealer. The manufacturer knows that future business is as firm as the realization that motor transport has come to stay can make it. The dealer should be impressed with this. The manufacturer should show him.

Do your bit by being at the show.

Abandonment of the Aero Show

AFTER considering the matter from every angle the committee in charge of organizing another aero show for New York City has decided to drop the project. Government departments apparently looked with some disfavor on the plan, and it is hardly possible that the aircraft industry was greatly interested, in view of the fact that all established firms are rushed to the limit with work. Just now, also, there is no need to stimulate public interest by artificial means, as aircraft development is receiving all needed encouragement through Government channels.

One reason mentioned in connection with the abandonment of the show is that it would have been an unnecessary tax on our transportation system, which is already strained to its limit. It would have been necessary to carry much bulky material from the factories—many of them located far inland—and back again, and show attendants and out-of-town visitors would have added to the passenger traffic.

No show made up exclusively of historical and experimental exhibits would have served its purpose and satisfied the public. It would have been necessary to secure the co-operation of leading firms of the industry, and preparation of the exhibition material at the plants of these firms might have interfered with production on Government orders, which would have been impermissible.

Therefore, while it cannot be denied that the proposed show promised certain beneficial results, as outlined in these columns some months ago, it is undoubtedly to the advantage of both the national and the aero industry that no show be held this year.

Tractor Service

WHEN an automobile owner complains to a dealer regarding some trouble with his car, the latter will often say: "Drive her around to our service station some day and we will have one of our men look her over." Such a proposal generally appeals to the owner, because he is most likely to come by the station anyway in his driving, or even if he has to go out of his way say 5 miles, it is only a matter of a few minutes.

It is an entirely different proposition with the tractor, however. In the course of its regular use the farm tractor never comes to town. It is a very slow vehicle and road travel is particularly severe on it. Moreover, during the period of its most in-

Digitized by Google

tense use, when it is most likely to require the attention of service men, the farmer is exceedingly busy and cannot spare any time from his work. The very fact that the service man on his motorcycle or automobile can travel at least ten times as fast as the farmer with his tractor and needs to move only a small fraction of the weight makes it obvious that the service man must go to the tractor—that the tractor cannot be brought to him. This is, moreover, the practice with respect to other heavy, slow-moving farm machinery, such as seeders and binders.

It would seem that tractor service should open up an excellent field for the motorcycle. Ordinarily it is not necessary to carry much heavy equipment. What tools and instruments are required might be carried in a leather roll strapped to the machine, but if this does not suffice a side attachment with carrier box would give all the carrying capacity needed.

It is true that the farmer has learned a great deal about gasoline engines and kindred mechanism by his experience with pumping engines, automobiles and lighting sets, but the day where he can do without the service of the expert is still far off. The fact that the tractor is tied to the field, so to speak, that it cannot be taken great distances to machine shops, makes it necessary to organize service for it on an even more elaborate scale than for automobiles.

Economy in Transportation

THE world-wide wave of economy cannot pass over such a fundamental of modern life as transportation. It is affecting every other phase of human existence and it cannot help but affect our mode of transportation as well. In fact it has already done so. Our railroads have been taken over by the government.

If the railroads are affected automobiles will also be affected. They will have to be operated more economically, and the cars of the future must be more efficient from a transportation basis than ever before. More miles of travel per dollar of expense must be given to the owner, better performance, better endurance, better service in every direction must come back to the purchaser of automobile transportation.

As a nation we are through buying cars, we are buying transportation itself. The car of to-day is not judged by any other standard than by the amount of transportation it provides and the quality of this transportation. If we have been extravagant in the past, we are now becoming economical. Our daily habits are undergoing a marked change. We are getting down to a war-time basis and our method of getting from place to place must be altered in conformity with the other changes that have taken place.

First cost as represented by the price mark on an automobile is not necessarily effected by this change in viewpoint. The only difference is that buyers are going to scan more closely the return for their money and if the difference between a low-priced car and one that is higher priced is made up in better performance, in better service, in more comfort, the price mark alone is not going to serve as a barrier. Useless extravagance in weight, engine size, gasoline consumption, tire wear and even in space required are all going to be checked. The 100 per cent efficient car would utilize every inch of wheelbase, it would have the lightest possible weight per pound of passenger load, it would utilize ever ounce of energy in the fuel, every bit of rubber in the tires and every bit of lubricating quality in the oil. We will never have the 100 per cent perfect car, but we must shoot as closely as possible to the mark to meet the changed demands of automobile buyers who no longer buy their vehicles by the pound.

The Coming S. A. E. Meeting

AS was the case at Washington last summer, the winter meeting of the S. A. E. in New York next week will be confined to a single day. As the most important engineering development in this country during the past six months has been the design of the Liberty aircraft engine and the design of the Liberty trucks, and as the S. A. E. has been closely connected with this work, it is fitting that these pieces of engineering work have been chosen as subjects of discussion. It will be interesting to the membership to hear directly from the men responsible for these designs the reasons behind their work. Neither the aircraft engine nor the motor truck is a one-man job and we presume that all of the features involved were fully discussed over the drawing table, so that the chief designers are thoroughly familiar with all the pros and cons not only of the features adopted, but of others that might have been used instead. As it is seldom that engineers fully agree regarding the relative advantages and disadvantages of different constructions it is not unlikely that a spirited discussion will ensue when these subjects are taken up.

Much of the time at the coming meeting will be taken up with a consideration of the report of the Standards Committee. A bulletin containing the reports of the various divisions awaiting action at the Standards Committee meeting has just been issued and contains easily the largest number of items ever taken up at any semi-annual meeting. This increased volume of work of the Standards Committee results, of course, in part from the launching out into new lines and the appointment of new divisions, but it is also in no small measure due to more energetic management of the Standards work than prevailed in the past.

Wanted—Specialists

THE great need of specialized knowledge was never so keenly recognized as now. The talk about a shortage of skilled labor when boiled down to its ultimate state is nothing more or less than the result of the demand for specialists. We are not short of man power, and whereas the shortage of labor may be stated in terms of thousands, the shortage of specialists means the urgent need for a few hundred right men for the right jobs.

Search Reveals No Labor Shortage

Vanderlip's Theory Disproved by Figures Showing Army of Men Out of Work—Some Skilled Men Needed

NEW YORK CITY, Jan. 2—The Frank A. Vanderlip statement made in his speech-making tour a week ago to the effect that the shortage of overcoats by our soldiers was due directly to a labor shortage, and that much of this labor was engaged in what Mr. Vanderlip describes as industries not connected directly with the war, has been denied by figures furnished by the Clearing House of Labor in this city, which is an organization in touch with 100 employment bureaus throughout New York state. The bureaus in question are described as non-fee bureaus in that they do not charge any fee for placing a worker in a job. Morris L. Ernst, director of the bureau, says that in New York City alone there are 30,000 garment workers out of employment, so that with this number of idle garment makers the labor shortage referred to by Mr. Vanderlip does not exist.

Mr. Ernst gives some clue to the possible labor situation when he says that contracts for clothing have been given to concerns without factories, and that factories had to be built and labor moved in before production started. Such conditions must not be interpreted as meaning a shortage of labor, but rather a failure in bringing the worker and the job together.

Vanderlipian Theory Disproved

Mr. Vanderlip's Vanderlipian theory that there is a general labor shortage throughout the country and which he is talking so generally on in his war-saving certificate campaign around the country, has been unqualifiedly challenged by the Department of Labor in Washington, which calls Mr. Vanderlip's statements about such shortage not only untrue but unpatriotic and not common sense, because they tend to create a panicky condition in industries which is very injurious to our activities in the war. This is not the first time that the Department of Labor, which is closely in touch with labor conditions throughout the country, has blankly denied the statements being credited to Mr. Vanderlip on this subject.

At present there is no acute labor shortage in this country. The Western shipyards need 25,000 men and the Department of Labor knows where to get them at the proper time from west of the Mississippi. The Eastern seaboard shipping yards need a few men who can be secured in their home towns. In seven or eight months there will be a demand for about 40,000 skilled workers, and not 400,000 as some reports have it. The Department of Labor states it knows where to get these men without serious disturbance to any industry. The 40,000 skilled men needed will come from 30 different trades, one of which has 700,000 members, which shows how diversified the demand will be and how little it will affect any industry. The greatest present labor problem is that of man-adjustment and getting together the many ideal men who are found in some cities where many plants need them. The situation is common to almost every city in the country.

Mr. Ernst, speaking with regard to the labor situation in New York state, gives numerous figures that are illuminating on this subject.

An Army Out of Work

In New York City there are 500 expert jewelers out of work; it is reported that in Boston 1000 men in the same line are seeking employment. These men are experienced in working with delicate machines and in performing exact operations and yet great difficulty is being found in placing them in lines where experience of this nature would be invaluable. While searching for positions for these men, fifty-five plants were written to and only two needed any men. The Aircraft Manufacturers' Assn. reported less than 10 days ago that they have all the men they can use.

There is admittedly a shortage of specialists. This is always true regardless of any times and particularly so whenever a big change of conditions is taking place. Some of the employment agencies in large centers along the Atlantic Seaboard, such as New York City, for instance, have from 100 to 200 men looking for work every morning. One of the most noticeable points in this connection is the stand taken by those out of work in refusing to accept anything but the choicest kinds of positions at the most advanced prices. This condition is directly traceable to the stories which have been going forth that a shortage exists. Naturally this puts the idea into the mind of the laborer that he can command his own price with the result that he is loath to take anything that does not pay him more than would normally be expected.

A small item in a New York newspaper, dated Nov. 14, to the effect that a shipbuilding concern needed 2000 men brought scores of letters from all over the country requesting particulars. A large percentage of these men were skilled laborers seeking high class jobs. This is significant and shows that no shortage of man power exists at the present time.

Award Contracts for 4100 War Trucks

WASHINGTON, Dec. 29—Contracts for 4100 war trucks, to be delivered early in 1918, for service in the Aircraft Division of the Signal Corps, have been awarded. These include 2200 of the 1½-ton light trucks mounted on pneumatic tires and specially intended for high speed work, and 1900 of the 5½-ton trucks of similar design but mounted on solid tires. The contracts have been awarded as follows:

1½-Ton Light Trucks	
Signal Motor Truck Co.	500
Republic Motor Truck Co.	500
Denby Motor Truck Co.	500
General Motors Truck Co.	700
3½-Ton Heavy Trucks	
Standard Motor Truck Co.	350
United Motor Truck Co. (Grand Rapids)	250
Federal Motor Truck Co.	500
Kelly-Springfield Truck Co.	500
Velie Motor Co.	400

Plan Six More Truck Trains

DETROIT, Dec. 31—It is expected that six more United States Army truck trains, each consisting of thirty Packard trucks, will leave this city overland for the seaboard. The Packard Motor Car Co. has received an unofficial notice to prepare these trucks for the drive. The Government, however, is to supply the drivers, and these must be organized before the drive-away takes place. It is stated that the first trip overland was entirely successful and the trucks will soon be running on a regular schedule from the factories.

—

Airplanes Can Now Be Insured

WASHINGTON, D. C., Jan. 2—The National Advisory Committee for Aeronautics has taken up the subject of insurance for aircraft, and announces that it has arranged with insurance companies so that they will now insure aircraft against fire while in flight, on the earth, or on any lake or river in the United States. Caution is advised by the committee to avoid the congestion of hangars which are usually remote from fire protection.

—

American Tractor Corp. Formed

RICHMOND, VA., Dec. 31—The American Tractor Corp. has been organized with a capital of $1,000,000 to manufacture and sell traction engines. F. S. Crosby has been elected president and H. H. Chalkley secretary.

Class A Trucks Reach Washington

White, Denby and Autocar Vehicles Encounter No Difficulties En Route

WASHINGTON, D. C., Jan. 2—The three samples of Class A standardized war trucks which were manufactured in the White, Denby and Autocar factories, and were driven overland from these factories, arrived in Washington in good condition, none of them experiencing any mechanical troubles. The trucks, with load, averaged 5.3 miles per gallon, and their speed over the highways averaged 17 m.p.h. Governors were set to regulate the speed between 13 and 17 m.p.h.

The truck assembled by the Denby Motor Truck Co., Detroit, took 9 days for the overland trip. The one assembled by the White Motor Co., Cleveland, required 7 days from that city to Washington, and the one assembled by the Autocar Co., Ardmore, Pa., required 5 days for the trip. The Denby picked up the White at Cleveland, and these two in turn picked up the Autocar, so that all three arrived in Washington together.

The first AA standardized truck will probably be finished before Jan. 15, as per schedule. The parts for this truck are now almost complete.

Two models of the standardized A truck will be given a series of severe tests in and around Washington for several weeks. The third model of these trucks will be turned over to the drafting department.

—

To Fix More Steel Prices

WASHINGTON, Jan. 2—A bill meeting the ideas of the President as to additional legislation necessary to the fixing of prices of steel and iron is to be pushed vigorously and promptly by Senator Pomerene of Ohio. Senator Pomerene, who fathered such a measure during the special session of Congress, is to revive his bill, it is understood, and push it at once. He has had conferences with the President on the subject. The provisions of the bill probably will be extended to include agricultural implements, it is said.

—

Jackson Munition Corporation in Light

JACKSON, MICH., Jan. 3—The proposal to form a corporation to manufacture munitions here similar to the one recently formed in Detroit is slowly taking shape. Local manufacturers have appointed two committees to ascertain whether such a corporation would be preferable to manufacture by individual companies. One committee will investigate the formation of the Detroit corporation and the other will make local investigations. Two plants are being considered as suitable for the use of a shell corporation. One of these is the Jackson automobile factory and the other is the old Imperial plant.

—

Troy to Make Trailers for Government

TROY, OHIO, Jan. 2—The Troy Wagon Works Co. has received a Government order for 100 two- to five-ton Troy trailers of special design for the Signal Corps.

—

Lansing Companies Get Orders for Escort Wheels

LANSING, MICH., Jan. 2—The Prudden Wheel Co. and the Auto Wheel Co. have received Government contracts for escort wheels amounting to $3,000,000. The contracts must be completed by Dec. 31, 1918, and are proportional to the respective production capacities of the two companies. It is estimated that the Auto Wheel Co. will require 800 additional employees to complete the work in that time. Other big orders for the same type of wheel have been placed with the Kelsey Wheel Co., Detroit, and the Hayes Wheel Co., Jackson.

—

To Facilitate Grand Rapids Airplane Work

GRAND RAPIDS, MICH., Jan. 2—The Federation of Furniture Manufacturers here, to which about 300 local industrial plants belong, is appointing a sub-committee to act as a clearing house for Government orders. Peter B. Schravesa, president of the School Equipment Co., is chairman of the committee. Several million dollars' worth of airplane parts will be ordered, it is expected.

—

Stearns to Make Rolls-Royce Airplane Engines

CLEVELAND, Jan. 2—The F. B. Stearns Co. has received a contract stated to involve several million dollars for the manufacture of airplane engines for the British Government. This is a sub-contract under the British Rolls-Royce Co. and under it the Stearns Co. will manufacture Rolls-Royce engines complete except for a few minor parts. The contract will require several additions to the Stearns plant and a directors' meeting will be called this week to complete arrangements for enlargement. It is stated that though this contract will require some slight curtailment in the production of Stearns-Knight cars manufacture will be continued.

Prompt Unloading Is Mandatory

Railroad Dictator Threatens Dilatory Dealers with Embargo—The Situation

WASHINGTON, D. C., Jan. 2—Secretary McAdoo, who is now railroad dictator, has issued an order to-day to the effect that any consignee who does not promptly unload freight cars and release them for return trips will be embargoed. This order has a distinct meaning to the automobile industry, both to the manufacturer and the dealer. Many dealers had been receiving shipments of automobiles that they were not expecting from the factory and had made no provision for the immediate unloading of them, in which case the factory was at fault. If these unloading delays are continued the dealer will be embargoed. New England dealers have been constant violators of this unloading problem.

Many dealers do not realize how closely they are being watched in this work. There are twenty or thirty local committees of the American Railroad Association in different parts of the country. In the same cities there are other committees representing the national, industrial traffic league, which is the national organization of shipping interests. Both of these sets of committees work together. Flagrant abuses of dealers not unloading automobile shipments promptly are reported to the National Automobile Chamber of Commerce, but there are hundreds and thousands of cases which are not so reported. It is dangerous work for the dealer to delay an hour in this unloading work.

In addition to the two sets of committees watching the situation there are scattered throughout the country inspectors of the Railroad War Board who are moving about all of the time in search of violations of this unloading regulation.

The taking over of the railroads by the Government looks like increased railroad facilities, and can only be considered as beneficial to the general situation. The outlook is very favorable for the automobile industry in general, as the railroad dictator is not considering any move at this time that would injure any of the industries.

The policy is one of construction. The Railroad Dictator has issued orders creating genuine pooling of railroads, appointing capable assistants and promising an increase in wages to all railroad workers, requisitioning 1800 locomotives originally designed for foreign

Digitized by Google

service and ordering many lines not requiring their engines and cars to transport them to the congested districts.

Many passenger coaches will be converted into freight cars and additional freight terminals will be built as required. Common freight terminals will be arranged in Chicago, New York and New Jersey, and the Railroad Dictator also plans to construct many new tracks, freight cars and engines, all of which, it is hoped, will care for freight requirements of the war, aided by electrical lines, waterways and motor transportation without creating disturbance to any industry.

—

Fuel Situation Easier

DETROIT, Jan. 2—Although the fuel situation is bad here it is not expected that industries will be harmed to an alarming extent. Michigan Fuel Administrator W. K. Prudden has ordered that all emergency coal entering Detroit be used first to alleviate any shortage for domestic use and any surplus turned over to the industries. At present most industries are running at almost normal capacity though there have been some instances of shut-downs. Briscoe, for example, shut down 2 days last week and closed at 2:15 p. m. several days owing to lack of coal, but is running full time now. Oakland, in Pontiac, is short of coal but is running full time. Both Olds and Reo have plenty of coal for the present but the future looks bad.

—

Jobbers Ready for Convention

NEW YORK, Jan. 2—The third annual meeting of the National Association of Automobile Accessory Jobbers will be held Jan. 14-15-16 at the Hotel Astor in the North Ball Room on the eighth floor. These three days will be devoted to the open sessions of the association. Committee meetings will be held Jan. 11-12, the last two days of the New York show.

Commissioner William M. Webster, in the convention program, states that the association has continued to grow during the past year and enters 1918 with indications of continued steady growth. There have been about a dozen resignations, due, he states, to the discontinuance of manufacturers and to the attitude of the Ford Motor Co. in regard to its dealers acting as jobbers.

—

Stewart to Make Airplane Wheels

INDIANAPOLIS, Dec. 31—The Stewart Wire Wheel Corp. of Frankfort, Ind., has signed a Government contract to manufacture 4500 wire wheels for airplanes. Approximately $45,000 is involved in the order.

—

Gilette Brings $151,000

MISHAWKA, IND., Dec. 31—The Gilette Motors Co. has been sold to M. W. Mix, president of the Dodge Mfg. Co., and the sale has been approved by the South Bend Circuit Court. The consideration was $151,000. In July, 1916, the Gilette Co. was formed to take over the plant and patent rights of the Wilmo Co., accessory manufacturers, Chicago.

Detroit Calms Down Before Show

Coal Situation Relieved—Manufacturers Start for New York

DETROIT, Dec. 28—In spite of the abnormal conditions that have at times seemed to threaten the automobile industry, conditions in the past week have calmed down considerably, and manufacturers are preparing to attend the New York show and get ready for Spring business. Throughout the city and state the coal situation has eased up, due partly to the holidays, but more directly to receipt of coal shipments.

Recently 1800 carloads of coal arrived in Detroit, and there is a prospect of eight or ten times that amount arriving in the next ten days. Grand Rapids reports every dealer supplied, and 100 tons on hand. The Sparks-Withington Co., Jackson, says that though the electric power company has only a limited supply of coal on hand, they, personally, have sufficient. This company also states a more cheerful outlook on the part of manufacturers. Some time ago stop-orders on parts for manufacturers were more or less common, but recently orders have been coming in in a manner that indicates that makers are getting their nerve back, and going ahead on a square basis.

There is a strong possibility that the automobile and parts manufacturers of Jackson will form a shell company similar to that recently formed in Detroit. Last week Mayor Sparks, Jackson, received a telegram from A. W. Copland asking if the manufacturers would be interested in forming such a company, to which the manufacturers replied affirmatively. A survey of the companies will be made, and a committee may be sent to Washington to arrange the details.

The Harroun Motor Co., Wayne, is rapidly speeding up production, and is now shipping 30 cars a day. Freight car and coal shortage, hindering the Detroit manufacturers, is less acute in Wayne, and Harroun reports no difficulty in that direction.

During the past week the Liberty Motor Car Co. has shown a marked expansion in its dealers organization, and manufacturers are optimistic for the coming season. Among the new agencies established are: F. E. Styvesant Co., Cleveland, with branches in Toledo, and later in Columbus and Cincinnati; J. D. Moore, Walla Walla, Wash.; Twin City Motor Car Co., Minneapolis; Edgar F. Sanger Co., Milwaukee, and the Means Automobile Co., Des Moines.

As an example of the further working out of the drive-away problem, to relieve the freight car situation, two cases are cited whereby passenger cars have been delivered on trucks overland. In one case, three twin-six Packard enclosed cars were loaded on Packard 3-ton trucks, and started on Dec. 24 for Baltimore, a fourth truck carrying a passenger car body. The second instance is that of a Washington, D. C., cartage man who contracted to bring two Cadillacs with him on two Packard 3-ton trucks he was driving back for his own use.

—

Stevens Point for Trenam Tractor Site

STEVENS POINT, WIS., Dec. 31—The Trenam Tractor Co., Milwaukee, organized several months ago with $400,000 capital to manufacture a tractor designed by J. J. Trenam, has decided to establish its permanent plant and headquarters in Stevens Point. The company has purchased the entire plant and holdings of the Central City Iron Works, Stevens Point, consisting of a large malleable and grey iron foundry, machine and assembling shops, office and warehouse building. The first castings for the new tractor have been made already. The company will furnish parts to other tractor manufacturers and railroads.

—

Dump Bodies from Milwaukee

MILWAUKEE, Dec. 31—The Horizontal Hydraulic Hoist & Body Co. has been organized with a capital stock of $50,000 to manufacture automatic dump bodies and hoisting devices for motor trucks. Arrangements are now being made for the establishment of a factory in Milwaukee. Charles F. Millmann, Edward R. Bacon and Benjamin A. Reese are the incorporators.

New Erd Kerosene Engine

SAGINAW, MICH., Dec. 30—The Erd Motor Co. will manufacture a kerosene burning tractor motor larger than the present model. This will embody radical changes in design and have greater power and economy. The Erd plant will be expanded to give added facilities for the manufacture of the new tractor.

—

Phoenix Rushed with Government Orders

EAU CLAIRE, WIS., Dec. 31—The Phoenix Mfg. Co. is delivering a number of Phoenix Centipede tractor trucks to the United States Quartermaster's department in Texas for exhaustive army tests. The trucks were constructed under Government supervision and employ the well-known creeper-type driving principle.

—

Airplanes from Indianapolis

INDIANAPOLIS, Dec. 31—Preliminary incorporation papers have been filed by several well-known Indianapolis business men who intend to organize a corporation here to manufacture airplanes. The company has been capitalized at $1,000. The directors of the company include Albert D. Johnson, secretary-treasurer of the Diamond Chain & Mfg. Co.; A. B. Jennings, a real estate dealer; Lewis Wallace and Joseph T. Markey, attorneys, and George H. Cottrill, a lumber dealer.

First Motor Truck Train Completes Trip

Proves Feasibility of Motor Truck Transportation—Orders Issued to Companies to Use Highways for Drive-Aways

WASHINGTON, D. C., Dec. 29—The motor truck convoy which left Detroit Dec. 14 to make the first test overland drive-away to the Eastern seaboards arrived at Baltimore, its American terminal, yesterday. One of the 30 trucks starting the journey failed to finish, having been struck by a train en route. The trip marks the beginning of a new era of huge and vast drive-aways. Orders were issued immediately following the end of the journey by Major Miller to all motor companies shipping war trucks east to utilize the highways of the nation for drive-aways in all instances. The journey was made slowly under orders from the War Department, averaging 50 miles a day.

The complete convoy comprised 28 3-ton Packard motor trucks, 2 Packard oil tank trucks, a Dodge 5-passenger car, a Dodge roadster, a Dodge light delivery truck and a General Motors light ambulance truck. The personnel included: Capt. Bennett Bronson, Quartermaster Corps, in charge of convoy; Lieut. C. A. Riley, Quartermaster Corps, in charge of motor train; Lieut. L. J. Ward, U. S. M. C., medical officer in charge; eight National Army men; Capt. E. B. Butchers, representing U. S. Engineers Corps, and H. C. Ostermann, representing Highways Transport Committee.

The trip is particularly remarkable in view of the fact that none of the drivers has ever driven any truck before. They were all men taken from an infantry camp and placed at the wheel. Weather conditions were the most adverse possible. The convoy left Detroit at 4 below zero and fought through snow all the way up to Pennsylvania. Schools were let out along the route, business, military and professional men turned out to give welcome to the trucks and the Red Cross had hot meals ready for the soldiers at every stop.

The trip absolutely proves the feasibility of motor truck transportation in all kinds of weather. Following is an outline of the journey:

The U. S. Motor Transport left Detroit Dec. 14 at 10 a. m. from the Packard factory, proceeding through Detroit without difficulty as the streets were cleared of traffic and no deep snow was found. The transport arrived at Monroe, Mich., at 9 p. m. after laying 3½ miles west of Monroe 3 hours attempting to clear the route of snow. The distance covered the first day was 45 miles.

The transport arrived at Toledo at 5:30 p. m. without encountering any particular difficulty between Monroe and Toledo with the exception of short stretches where the road had not been dragged and light traffic had broken the drifts into a zig-zag line. No effort had been made by county officials to scrape off the roads. In many instances the road was broken on one side, covering a portion of the shoulder of the road, making it dangerous to heavy truck transportation. Distance on the second day 18 miles.

They left Toledo 7:30 a. m. Dec. 16, passed to Norwalk, Ohio, and arrived at 7:30 p. m. No effort had been made by the county and township officials to clear the roads and considerable snow drift trouble was encountered. The mileage of the day was 62 miles.

Leaving Norwalk at 8:20 a. m. Dec. 17, the convoy found the road, with a few exceptions, well cleared of snow and experienced no difficulty in reaching Cleveland at 6 p. m., covering 58 miles for the day.

It left Cleveland at 9 a. m. Dec. 18 and arrived at Ravenna, Ohio, at 5 p. m. The road showed some care but work had not been completed in an intelligent manner and many high centers were encountered. From Ravenna to Warren through misunderstanding the route was changed and 24 miles of bad roads were encountered. Later it was learned that officials had cleared the road on the original routing. Trucks arrived at Warren at 3 a. m., covering 65.5 miles.

On the route from Ravenna to Warren truck No. 21 was struck by a passenger train and the driver was killed. This necessitated laying over at Warren on Dec. 19.

The party left Warren at 7:15 a. m. Dec. 20 and arrived at New Brighton at 8 p. m., covering 54.8 miles. Considerable difficulty was encountered on that section of the road known as the "cut-off" between New Springfield and Unity. A little graveling had been done by Mahoning county and nothing at all by the Columbiana county. The stretch was narrow and a primitive dirt road. Three sharp right angle turns were found. After the trucks passed over the road, ruts a foot deep were left.

New Brighton was left at 8:20 a. m. and Pittsburgh reached at 2 p. m. Dec. 21. No difficulty was experienced over this 32 miles of the trip.

From Pittsburgh east the journey was made without difficulty, road conditions in Pennsylvania and Maryland being found in excellent shape.

Credit is given by members of the party to the State Highway Departments of Pennsylvania and Maryland for the remarkable condition of all roads. The last 232.9 miles were made in 7 days.

The trip was educational and resulted in a conference in Washington with the War Department about the lessons learned on the trip. The success of the trip is indicated by the fact that 6 similar truck trains have been ordered to leave Detroit next week, carrying supplies to the seaboard.

The snow organization was bad in Michigan and Ohio, but excellent in Pennsylvania and Maryland. The Highway Transport Committee would like all highway departments to remember that motor truck trains of this kind demand a wider clearance of the roads than passenger cars.

Europe's Post-War Models

Fiat, Renault, Berliet and Others to Get Into Large Production on Medium-Priced Machines

PARIS, Dec. 10—Reports of huge after-war schemes in French motor circles have been prevalent for a long time, but few definite announcements have been made. Now comes the news that the Berliet company of Lyon, France, has formed an auxiliary company, with a capital of $5,000,000, with the intention of building and putting on the market a popular automobile, to be built in series of 30,000 and sold complete at $1,200.

No official announcement has been made regarding the type of car, but it is well known in automobile circles that Berliet has closely studied American production methods, that he has had in hand all the popular American cars, and that experimental models on these lines have been built. Thus it is safe to assume that the $1,200 car will be a six-passenger touring model with electric lighting and starting. It is obvious, too, in view of European taxation and gasoline cost, that it will have a small, comparatively high-speed four-cylinder motor.

While not the biggest in Europe, the Berliet factory, located at Lyon, is recognized as one of the most modern in France. Marius Berliet, the proprietor and founder of the firm, is a self-made man who got into the automobile business in 1899 with three workmen and a capital of $900. Before the war the factory covered 720,000 sq. ft., employed 2000 workpeople and produced 3000 cars a year. The works have grown enormously since 1914, the number of workers now being about 8000. For some time Berliet has specialized on trucks, and thus has kept his works on automobile production during the war. An additional factory is to be erected for the production of the popular after-the-war model.

There are several other firms capable of carrying out a program as big as that announced by Berliet. Fiat Co. at Turin, Italy, for instance, could certainly produce between 40,000 and 50,000 cars a year if the whole of the present factory were concentrated on one model. This company, which claims to be the biggest automobile concern in Europe, has a factory area of 5,400,000 sq. ft., a staff of 25,000 workpeople, and a nominal capital of $10,000,000. In addition it has recently absorbed the Ferriere Piemontesi Steel and Iron Foundries, Rolling Mills, etc., with a capital of $1,800,000; the Officiene Gia Fili Diatto (Tramways and Rolling Stock Works), with a capital of $800,000, and The Industrie Metallurgiche Torino Steel and Iron Works, with a capital of $800,000.

Fiat has not made any announcement of its post-war program, but is already putting out for war service five-passenger cars built on American lines complete with electric lighting and starting. Like Berliet, Fiat has kept on automobile work throughout the war. The Ital-

Digitized by Google

ian factory has taken advantage of war conditions to make itself independent of all outside concerns; thus it is producing practically every part of its cars, including electric appliances, but excluding magnetos in its own factories. It is reported that even magnetos will be Fiat produced after the war. Fiat has also developed the practice of building a large number of its own machine tools and special factory machinery.

In addition to Fiat there is in Turin a branch concern known as the Fiat San Giorgio, interested in Diesel motors, submarines, aviation motors, etc. This was originally a part of the main Fiat company, but during the past year the Fiat San Giorgio has secured financial independence.

Another firm expected to play an important role in the after-war competition is Renault, of which Louis Renault is the sole proprietor. This factory is now the biggest in France, with a staff of rather more than 20,000 workpeople, engaged on aviation motors, trucks and staff cars. Louis Renault, who started in the automobile business in 1898, in partnership with his two brothers, now dead, and a staff of about half a dozen workpeople, understands American production methods better than any other man in France, for he has made a number of visits to the United States and closely studied automobile conditions there. Up to the war, however, he had refused to break away from the European plan of building a variety of cars to suit the various classes of society. Rumor has it that Renault will put his big factory on the production of one or two popular models to be sold at a popular price. Only one man knows whether this is so or not—and Louis Renault is not talkative.

Reports are busy around the name of Citroen & Co., a firm which before the war made a specialty of gears and gear cutting, not only for the automobile industry but for general engineering. This factory has grown until the staff employed is about 15,000, and if reports can be believed Citroen will make a bold bid in the automobile business.

—

More Liberty Contracts for General Motors

DETROIT, Jan. 2—It is understood that the contracts for Liberty airplane engines now held by the General Motors Corp., and being filled by the Cadillac and Buick companies, have been extended. It is stated that these two companies have received new contracts which call for the completion of 50 Liberty engines a day for an indefinite period. The original order was for 1000 engines.

—

Women Taxicab Drivers

SEATTLE, Dec. 24—The Seattle Taxicab & Transfer Co. has employed 20 women as taxi drivers, to replace men who have joined the army. More women will be employed as vacancies occur. The new drivers will take the city examination and will be admitted to the Auto Drivers' Union.

Gasoline Allowance Cut in France

11 Gallons Per Month Allowed —Taxicab Use Restricted— Used Cars Drop

PARIS, Dec. 8—With the first day of January French motorists are to be deprived of all gasoline supplies and will receive no more permits to travel, thus making it impossible for them to use up any stocks they may have collected. The maximum gasoline allowed per month will be 11 gallons. This is the summary of a decree issued this week by the authorities and published in the *Journal Officiel*. The new decree puts France on the same footing as England and Italy, where for a few months private motoring has been forbidden. The situation of France is likely to be worse that that of England, for car owners in the latter country have found a certain measure of relief in the use of coal gas carried in rubber containers. This is not possible in France owing to the shortage of coal.

While the general principle of the decree is a complete cessation of motoring, it has been necessary in the interest of the nation to make certain exceptions. Thus the prefects are authorized to issue gasoline cards to persons running public service vehicles or doing work of national importance. This will cover doctors, farmers, business men whose business is necessary to the public, and public officials. It is obvious, too, that there must be a certain number of automobile owners who are completely dependent on the use of an automobile and could not exist without a car or some other means of locomotion. These cases will be considered on their merits, but the maximum amount of gasoline to be allowed in each case is fixed at 11 gallons per month. Up to a few weeks ago the allowance for private motorists was 66 gallons per month.

Ever since the war it has been necessary to have permit to travel by automobile in France. The deliverance of these permits, however, was a mere formality, and in the absence of police on the roads the official piece of paper was not even necessary. With the new year the travel permits will be entirely parochial, so that no automobile owner can get beyond his own immediate neighborhood. Further, the permits to purchase gasoline and the permits to travel will be given out together, a control being kept over the two, thus preventing gasoline being obtained by fraudulent purposes or the use of stocks which have been got together in normal times.

For long-distance touring the same regulations will apply, the authorities issuing the pass when they consider the journey is necessary in the national interests, or is made to transport sick or wounded. A clearly defined route must be followed, and the home trip must be made within a month.

The immediate result of these regulations will be to bring down the price of second-hand cars from the giddy heights they have attained to a more reasonable basis. As an indication of the exaggerated prices a used Rolls-Royce touring car changed hands a few days ago at $9,000, while all the cars discharged from the army as unfit for further war service have been sold to the public at very high figures.

There must be several thousands of small manufacturers and factory owners whose businesses have grown to such an extent that they now find it necessary to use an automobile. Many of these are old touring cars converted to light trucks, which are being worked to destruction with the maximum load on the body and a trailer in the rear. These men must either have gasoline or must limit their activities. It remains to be seen how the Government officials will take care of such cases. There is certainly a wide difference between the liberality of 1916 and 1917 and the proposed restrictions of 1918.

Taxicabs are to be given a special allowance of gasoline,, but they cannot be taken more than 3½ miles from the district in which they are licensed. Thus, in the case of Paris taxicabs, it will be impossible to go more than 3½ miles beyond the city walls.

—

Gasoline Exports Drop

WASHINGTON, Jan. 3—Exports of gasoline from the United States fell off approximately 24,000,000 gal. during the first 11 months of 1917 as compared with the same period in 1916. Exports of lubricating oil on the other hand increased nearly 27,000,000 gal. Crude oil fell off about 11,000,000 gal. Following are the figures:

Nov. 1917	11 mos. 1916	11 mos. 1917
	Gasoline, Gal.	
56,996,017	332,105,215	308,917,887
	Lubricating Oil, Gal.	
25,145,639	244,284,558	271,733,613
	Crude Oil, Gal.	
7,444,253	158,534,638	147,942,870

German Plot Injures War Trucks

WASHINGTON, D. C., Dec. 29—What is claimed to be a German plot was discovered by the War Department, in the injury of 600 war trucks recently ordered and delivered to this city. Upon reception of the trucks they were subjected to the usual examination. Pistons were found to be slightly out of plumb and they were sent back to the factory for correction. They returned with a slight knock, and an investigation by the secret service revealed that a German foreman who headed the machine shop where the trucks were had contrived to put them out in defective condition.

—

Stutz Engines—Correction

The Stutz Motor Car Co. manufactures only cars with 4-cylinder, 16-valve engines, and an item to the contrary in AUTOMOTIVE INDUSTRIES of Nov. 29 was incorrect.

Curtiss Bond Issue of $15,000,000

To Simplify Advances from Government and Retire Present Outstanding

BUFFALO, Dec. 30 — The Curtiss Aeroplane & Motors Corp. will issue $15,000,000 of first mortgage 6 per cent bonds, in 6 series, on Jan. 1. This is to simplify the process of securing advances from the Government through the War Credits Board, which are to be made for assisting its production on war contracts.

Series A, of $359,000, maturing Jan. 1, 1919; Series B, of $356,000, maturing Jan. 1, 1920; Series C, of $348,000, maturing Jan. 1, 1921; Series D, maturing Jan. 1, 1922, and Series E, of $1,982,000, maturing Jan. 1, 1923, will be used to retire, on a dollar-for-dollar basis, the present outstanding 6 per cent notes and the gold 6s of 1927. With the shortened maturity, no difficulty is expected, especially as the new notes, like the old, are convertible into common stock at $50 a share, and callable at 102½.

Series F, not convertible, and redeemable at par, is neither to be issued nor sold, but deposited with the Government as collateral against the expected advance upon contracts, in order to provide the "proper security" required by law in case of a Government advance. Officials of the company explain that the entire plan is not, strictly speaking, a new financing operation, but is merely intended to simplify the company's financial position in respect to the funded debt, preparatory to the Government's advance on contracts. This advance became necessary to give the company a free hand and plenty of working capital for the near future, as the labor of financing its new plant had imposed a heavy strain upon the company's resources.

—

Reo Shipping 125-150 Cars a Day

LANSING, MICH., Dec. 31—Daily shipments of the Reo Motor Car Co. average from 125 to 150 cars and many of these are being driven overland by dealers. Part of these cars are being taken by the dealers and stored at points near Lansing in the hope that the freight car situation will ease up slightly and permit them to be shipped to their ultimate destination. When and wherever possible drive-aways will, however, be used.

The Reo Motor Car Co. is tooling up preparatory to the manufacture of tractors for the United States Government. It is stated that this work will not materially reduce the production of the Reo company, as it works in nicely with the equipment and labor at hand. Hence the Reo dealers throughout the country will suffer no particular hardship. There are at present about 3500 cars on hand ready for transportation providing the equipment were available and officers of the company state that the recent Government control of railroads will doubtless better the freight car situation. This will be particularly due to the fact that any particular railroad equipment may be sent in any desired direction when needed—a condition that has been impossible in the past.

—

Kissel Released from B Truck Contract

WASHINGTON, D. C., Dec. 29—The Kissel Motor Car Co. has been released from its contract for 500 Class B heavy duty war trucks because of its need for all facilities to handle more recent contracts for four-wheel-drive trucks. The contract for the 500 B trucks was transferred to the Garford Motor Truck Co., making the Garford contracts for B trucks total 1000. It is rumored that two or three other concerns will also be released from their contracts.

—

Lang to Build Bodies

CLEVELAND, Dec. 27—The Lang Body Co. is completing its building and expects to start production by Feb. 1. The first unit, a three-story, L-shaped building of mill construction and the dry kiln is practically finished. The work is about thirty days behind schedule due to unusual weather conditions.

The company now has in stock lumber, aluminum and steel for the manufacture of commercial and passenger car bodies. The plant occupies five acres of land on the switch of the New York Central near West 106th Street and has an option on five adjoining acres. The officers of the company are: President and treasurer, Charles E. J. Lang, formerly vice-president and treasurer of the Rauch & Lang Carriage Co., and later vice-president and director in the consolidation of the Rauch & Lang Carriage Co., and the Baker Co.; vice-president and general manager, Elmer J. Lang; secretary, John H. Price. L. L. Williams, formerly with the body department of the Peerless Motor Car Co., is engaged in similar work in the Lang company.

—

New R. & L. Electric Model

CLEVELAND, OHIO, Dec. 31—The Baker R. & L. Co., manufacturers of the Rauch & Lang electric car, has developed a new model chassis styled W-42. This has a wheelbase of 142 in. and new body design. The construction is practically the same with several improvements incorporated including a more powerful motor. Three body styles are offered, a touring car, sedan and limousine.

—

Monroe Lowers Its Prices

PONTIAC, MICH., Dec. 31—In spite of the continually increasing cost of material the Monroe Motors Co. is decreasing the price of its product for 1918. The model N-6, four-cylinder touring car, previously cost $1,095 and this has been reduced $100 for the coming year. The sedan body, mounted on the same chassis, sells for $1,850. The reason stated for this decrease is that an increased production renders the reduction in price possible.

Truck Makers Try Drive-Aways

J. C. Wilson Co. and Dodge Will Follow Policy All Winter

DETROIT, Jan. 2—Truck manufacturers are following in line with passenger car manufacturers and using the drive-away method of getting trucks into dealers' hands. The J. C. Wilson Co. is having drive-aways to cities as far away as Boston, Philadelphia and Baltimore. Members of the firm say that in spite of road conditions saving in time and expense is considerable, even though freight car equipment were available.

Careful records of the last drive-away to Baltimore were kept. Each truck, of the 2-ton type, carried parts for the Baltimore service department. The distance of 543 miles was covered in 4 days, via Toledo, Cleveland, Youngstown, Pittsburgh, Uniontown, Cumberland and Baltimore. The average number of gallons of gasoline consumed was 52, with 1 gal. of oil. The total expense per truck, including insurance and mechanical wear proportional to yearly overhead, was $62.91; the cost per day, $15.56; the mileage cost, 11.6 cents, and the ton-mileage, 5.8 cents.

Dodge Brothers are likewise delivering their new commercial car overland, and this policy will be followed all winter, regardless of weather conditions. Already cars have been delivered to Lawrence, Kan.; Atlanta; Hannibal, Mo.; Paris, Tenn.; Waterloo, Iowa; Cincinnati; Davenport, Iowa; Johnstown, Pa.; Terre Haute and Chicago.

—

Jones to Have Continental Engine

WICHITA, KAN., Dec. 27—Jones cars and trucks will have Continental engines. A contract has been signed, by which the Continental Motor Co., Detroit, will supply engines for the new 27 A-B-C series and the 1 and 2-ton trucks. Model 26 A-B-C will continue with the Lewis engine.

—

Maxwell Preparing for Government Work

DETROIT, Dec. 31—The Maxwell Motor Co. is taking on tool designers, tool makers and die makers, and otherwise preparing for filling the Government contracts which it now has on hand. Due to the large amount of Government work at present being placed in production there is a premium placed on this class of skilled labor and it is difficult to obtain it even then.

—

Government Work for McFarlan

INDIANAPOLIS, IND., Dec. 31—The McFarlan Motor Car Co., Connersville, has signed a contract with the Government for the manufacture of 6,000 automobile tool chests. Officials of the company state that the order will keep the plant in operation to full capacity for several months.

France to Receive 1500 Tractors

Will Plant 1,500,000 Extra Acres of Wheat and Potatoes

WASHINGTON, Jan. 2—Fifteen hundred farm tractors will be sent to France by the Food Administration. All will be over-seas for spring plowing in March. It is estimated that this increase in the French food supply, through greater efficiency, will release 2,000,000 tons of shipping in 1918 that otherwise would be needed to transport food. France in 1917 had 30,742,157 acres of crops, compared with 40,657,293 in 1913. The total food crop in 1917 was 24,581,290 tons as compared with 30,462,340 tons in 1913. The tractors will enable the French to plant 500,000 additional acres of potatoes and an extra million acres of wheat.

The plan for sending the tractors was conceived by Henry Morgenthau and his son, Henry Morgenthau, Jr., the latter of whom will supervise the delivery of the tractors in France and establish schools to train older men and women to use them. The French government has accepted them and they will be distributed by the French Minister of Agriculture. The National Implement and Vehicle Association approved the plan and gave assurance that it would not interfere with American farm production.

—

Washington Has New Car Licensing Law

WASHINGTON, Jan. 2—Washington's new motor car law, providing for the yearly licensing of cars, which was enacted by Congress last session, went into effect Jan. 1. Motorists will have the entire month of January in which to procure their numbers, owing to the inability of the officials to secure numbers fast enough. The new registration law bases the tax on horsepower and the S. A. E. rating has been adopted. The rates are: 24 hp. and under, $3 per year; 30 hp. and less, $5; over 30 hp., $10; demonstrating cars of dealers, flat rate of $6 each; motorcycles, $2. Heretofore the tax was $2 per car and was good as long as the person to whom it was issued owned the car. Maryland is the only state in the union that has no reciprocity agreement with the District of Columbia. Motorists in that state will be compelled to take out licenses here if they desire to come into the District of Columbia.

—

Goodyear Profits Increase 100 Per Cent in 1917

NEW YORK, Jan. 2—Last year was the most successful in the history of the Goodyear Tire & Rubber Co. Gross sales jumped from $63,000,000 in 1916 to $111,000,000 in 1917 and net profits from $7,003,330 to $14,044,206. This shows an increase of 74 per cent in volume and 100 per cent in profits. Of this amount less than 1 per cent resulted from war business. The plant capacity of the company was almost doubled during the year.

—

Reilly Goes with Globe

SAN FRANCISCO, Jan. 2—W. P. H. Reilly, Pacific Coast sales manager of the Ajax Rubber Co., has resigned to become special representative of the Globe Rubber Tire Mfg. Co.

This change followed when J. C. Matlack accepted the presidency of the Globe Co. Reilly has been associated with Matlack for many years.

—

To Make Reversing Oil Engine

MILWAUKEE, Dec. 31—The American Oil Motors Co. is being organized with a capital stock of $1,000,000 by members of the Corporation Finance Co., 309 Caswell block, to manufacture an internal combustion engine designed by Charles S. Salfeld. This is capable of using the heaviest oils and distillates as fuel. The engine is designed for application to all kinds of vehicles, tractors and airplanes and is a reversing type. A. C. Lingelbach, Milwaukee, is handling the details of the promotion.

—

50 Trucks Overland from Buffalo

BUFFALO, Jan. 1—Fifty Pierce-Arrow army trucks left to-day overland for New York. This is the largest convoy ever started out in this way. The convoy of trucks which recently went from Michigan to Baltimore numbered 30. The first truck is fitted with a snow-plow and the engineers were fitted out with winter clothing by the Buffalo Red Cross. Captain J. D. K. Loach, Twentieth United States Engineers, is in charge of the trucks and the 92 men who operate them.

—

Syracuse Plant for Smith Wheel

SYRACUSE, N. Y., Dec. 31—The Smith Wheel, Inc., will increase its capital from $100,000 to $3,000,000 and take over the Globe Malleable Iron Co. The latter is the oldest manufacturing plant in Syracuse. Both companies are working on war orders.

—

Carrell Appointed Chief Engineer

SAGINAW, Jan. 2—William A. Carrell has been appointed chief engineer and works manager of the Erd Motor Co., Saginaw. He will also direct the sales and advertising. Formerly he was associated with the Wisconsin Motor Co., Milwaukee, and general superintendent of the Beaver Mfg. Co. and superintendent of the Milwaukee plant of the International Harvester Co.

—

Sweet Is Captain in Aviation Section

GRAND RAPIDS, Jan. 2—George P. Sweet, manager of the United Motors Co., Grand Rapids, has been commissioned a captain in the aviation section of the signal corps.

Detroit Feels Need of Specialists

But Shortage of Highly Skilled Men Will Not Seriously Hamper Production

DETROIT, Jan. 3—As has been the case for some months, there is a scarcity of what might be called specialist labor in Detroit, by this being meant such artisans as tool designers, tool makers, die makers, gage inspectors, time study experts, factory layout men, and chief inspectors. Although there is a scarcity of these specialists there is no danger of this condition delaying war materials getting into production. Chester M. Culver, manager of the Detroit Employers Association, an organization handling 225 Detroit concerns, states that there will not be any delay on production due to these causes.

It is these men who make the tools and equipment necessary for the production of all war materials, but after these tools are made comparatively unskilled labor can be used in the actual production. From that time on a small force of skilled men is required to keep the supply of tools, jigs and fixtures up to normal, and the others can be released for subsequent tool making.

The Government is taking many of these skilled laborers directly into their arsenals. Recently representatives were here from Watervliet, and to-day several were here from Rock Island, Ill., for the same purpose. The Government furnishes the gages, etc., for the manufacturer of munitions, and these representatives complain that unless they get men the work on the actual contracts will be greatly delayed, as that work cannot go ahead until the gages and fixtures are at hand.

At present every tool shop in the city needs tool makers, and practically all the manufacturers are advertising and desiring the same kind of labor. The statement that this kind of labor is not to be permanently required is demonstrated by the fact that the Rock Island arsenal representative does not desire these men for more than 2 or 3 months, and suggests that their families be left in the city, for after that time unskilled labor can take up the work and carry on the production.

Culver states that the building trades will supply many men for production work, as these trades are very quiet today. In their own field these men are experts, and hence readily pick up the small amount of training required in manufacturing munitions. Dilution of labor will relieve the problem once we are in production. This simply means that unskilled men and women will be trained to do one part of the production work in an expedient manner, the skilled workmen being used to check up the work and keep the tools in order.

It is stated that Frank E. Vanderlip's talks and newspaper articles did not take this fact into consideration, for an im-

Digitized by Google

mense amount of the production can be done by unskilled labor and skilled men are only needed to prepare the tools and later a few to maintain the equipment, but more time will be required to get into the actual production, because of this scarcity of skilled labor.

Many thousands of workmen will be needed in the city. It is estimated that Dodge Brothers' plant will require from 8000 to 10,000 men, that of the Lincoln Motors will require from 5000 to 7000 men and women, and the Detroit Shell Co., the Fisher Body Co., the Packard Motor Car Co., the Cadillac Motor Car Co. and the Maxwell Motor Co. will require many thousands more. But once in production by the dilution of labor the situation can be satisfactorily handled.

—

Northway in New Vehicle Company

BOSTON, Jan. 4—The Northway Motors Corporation has just been formed here and has secured a charter from the State to manufacture cars and trucks. R. E. Northway, formerly head of the Northway company of Detroit, that made motors, transmissions, rear axles, etc., and was taken over by General Motors in 1909, has come East to be chief engineer. Senator James E. Cavanagh is president; James E. Finneran, head of a big drug company, is treasurer, and some men prominent in other lines comprise the board of directors. The company has been incorporated for $5,000,000. The plant will be located in Boston.

—

Another Motor Mail Route

LOUISVILLE, Jan. 2—An automobile mail route will be established between Cave City, Ky., and Louisville. It previously has been announced from Indianapolis that a similar route from Louisville to Indianapolis would be established. This plan is being tried out by the government to enable farmers to market their perishable and other products. If these routes prove successful the system probably will become universal throughout the country. By Feb. 14 the routes will be ready for business, it is thought.

From Louisville to Cave City is a distance of 88.8 miles. An automobile will leave Louisville and Cave City at 5 o'clock each morning except Sunday and will have reached its destination by 2 o'clock in the afternoon. The Dixie Highway will be traversed and the following towns reached on the Cave City route: Shively, West Point, Elizabethtown, Upton, Bonnieville, Munfordsville, Rowletts and Horse Cave.

Towns which the route between Louisville and Indianapolis will pass through include New Albany, Bennettsville, Borden, Salem, Vallonia, Brownstown, Seymour, Janesville, Columbus, Taylorsville, Edinburg, Franklin and Greenwood.

Daily trips between Louisville and Indianapolis are planned. The automobiles will be "post-offices on wheels." One will leave each of the two cities at 4.30 o'clock in the morning and reach its destination at 6 o'clock in the afternoon.

Postmaster Schmitt will accept bids for carrying on the work under government contract.

G. M. Earnings Are $12,900,000

Represent 4 Months Profits and an Increase of 43.4 Per Cent Over That of 1916

NEW YORK, Jan. 2—During the 4 months ended Nov. 30, 1917, the General Motors Corp. earned undivided profits of $12,900,000. This compares with $8,993,633 in the same period of 1916, an increase of $3,906,367, or 43.4 per cent. This figure of profits, after allowing for proportionate preferred dividends, but before allowing for war taxes, amounts to 15.1 per cent on the $82,500,000 common stock outstanding for the four months' period.

No official estimate will be available for General Motors war taxes until further rulings are made, but in entirely unofficial quarters taxes are estimated at a maximum of $8,000,000 per annum, which for the four months' period would work out about 3 per cent on the common stock. On this basis of calculation, General Motors in four months, after proportionate taxes and preferred dividend requirements, earned a surplus equal to 12.1 per cent on the common stock.

Sales in the four months ended November amounted to 72,923 cars and trucks against 52,868 in the same period of 1916. Net sales for the period were $74,868,000 against $48,383,997.

Cash in the bank and sight drafts with documents attached as of December 18, 1917, amounted to $23,530,000.

Comparison of results for the four months ended November 30, 1917, with the corresponding period of 1916 follows:

	1917	1916	Increase
Cars & trucks sold	72,923	52,868	20,055
Net sales	$74,868,000	$48,383,997	$26,484,003
Undivided profits	12,900,000	8,993,633	3,906,367

—

Navarre to Attempt Flight Across Atlantic

PARIS, Dec. 22—Jean Navarre, who, until his mad exploits which brought him in contact with the Paris police, was the best aviator France possessed or ever had possessed, has just announced his intention of making a flight across the Atlantic. For several months now Navarre has been in disgrace. After his foolish escapades in Paris he was brought before the military courts, where it was pleaded that he was not in full possession of his mental faculties, the solution of the matter being his discharge from the army. According to *l'Echo des Sports*, in which journal Navarre has confided, the famous aviator is completely cured of his youthful wildness and is determined to retrieve his reputation.

In the present stage of aviation a flight across the Atlantic is just within the range of possibility, but the risks are so great that it needs a man of the daring and audacity of Navarre to make the attempt. Two methods are possible: A fast, light, scout type of machine capable of an average speed of more than 125 miles an hour; such machines exist; and a big slow machine, of the Handley Page, Gotha, or Caproni type, averaging between 80 and 90 miles an hour.

Navarre is in favor of the latter type of machine, which he considers should be fitted with four engines of 300 hp. each, and should carry three men, who will be both pilots and mechanics.

The shortest route across the Atlantic is about 2500 miles, thus with an 85 miles an hour machine the flight would last 30 hours, and each of the three men would undertake two periods of piloting of five hours each. After the first 5 hours at the wheel, the pilot would look after the engines for 2½ hours, then rest for 7½ hours, and at the end of this time would take his place at the steering wheel.

The weight of the machine, with supply of fuel, oil and provisions for a flight of this length is estimated at 12 tons. It is intended, at the outset, to use all four engines. At the end of ten hours, when the consumption of fuel will have reduced the total weight to 9 tons, it is intended to run with three engines, thus maintaining the same average speed with a lower consumption of fuel. At the end of another ten hours, when the weight will have reduced to 6 tons, a second engine will be stopped, and the flight finished with two engines only, developing 600 hp.

The machine will be a biplane hydroplane with two of the motors carried in the fuselage and one each to the left and right, on the wings. The bearing surface will be more than 3000 sq. ft., the wing span about 108 ft.

—

Louisville Show Abandoned

LOUISVILLE, Jan. 2—No show will be held this winter under the auspices of the Louisville Automobile Dealers' Association. This was decided last week at the annual meeting of the organization after carefully considering a committee report that the First Regiment Armory could not be obtained, as it is being used for government purposes. There is no other building in the city suitable to house an exhibition of such magnitude.

The following officers were elected to serve during the coming year: Prince Wells, president; W. A. Thomas, vice-president, and Philip S. Longest, secretary.

—

Jordan Earns at Rate of 66 Per Cent

DETROIT, Jan. 3—The statement of the Jordan Motor Car Co. for the quarter ending Jan. 1 shows an increase of 30 per cent in the number of cars sold, compared with the corresponding period last year. Net car sales for the last quarter of 1917 totalled $571,232. Sales of parts amounted to $19,593. The cost of cars amounted to $500,746. The total cost of doing business was $540,524. The net profit was $50,302.55 and the total income $590,826. This represents 16.7 per cent on $300,000 preferred capital for the quarter at the rate of 66 per cent for the year.

New York Exports $9,481,394

November Shipments to Allies Largest Factor—England Gets 971 Trucks

NEW YORK, Dec. 27—Exports of passenger cars, trucks and parts from this port for November totaled $9,481,394. This includes shipments of 1403 passenger cars, valued at $3,844,194, and 1403 commercial vehicles and motor trucks valued at $3,446,072. The value of parts exported was $1,921,595.

Russia was the largest purchaser of passenger cars, 202 cars valued at $454,781 being shipped there from New York. Australia's purchases rank second and amount to 551 cars valued at $437,310. The average value of the car sent to Russia is 3 times as great as that sent to Australia. England leads in the number and value of trucks exported, having purchased 971 commercial vehicles and motor trucks valued at $2,316,478. France ordered 106 trucks at $297,146.

Our shipments to the Allies were by far the largest factor in export trade from the port of New York. These amounted to $4,598,819. The next largest customer was South America, whose bill was $1,286,310.

—

$1,000,000 More Taxes from Motorists?

BOSTON, Dec. 29—A plan to collect $1,000,000 in taxes from Massachusetts motorists to replace a similar amount appropriated for road maintenance, but needed for other Government expenses, was given wide publicity yesterday. A short time ago a commission appointed to raise revenue told the Highway Commission that the commonwealth was in need of more money, and that $1,000,000 of the amount held by the commission for road maintenance should be turned into the state treasury and an extra tax of $5 per vehicle and $3 on operating fee be collected to make up the loss. The commission pointed out that the money had been appropriated for road maintenance and could not be used for anything else. The Boston Automobile Dealers' Assn. called together the heads of all motor organizations and a letter of protest against the passing of such a law was sent to Governor McCall, who, it is understood, plans to embody the suggestion of the Revenue Commission in his annual message to the legislature on Jan. 2.

—

Detroit Shell Co. Has Option on Springfield Plant

DETROIT, Dec. 28—A meeting of the Springfield Body Corp. and the Springfield Realty Co. was held to-day by the referee in bankruptcy to show a cause of action in the re-sale of the property. The actual sale of the plant of the Springfield Body Corp. has not yet taken place. However, the Detroit Shell Co., recently organized by Detroit automobile makers and financiers, has an option on the plant. At present the affair is pending the action of the Detroit Shell Co.

To Start 4,000-Mile Mail Route

Post Office Department Will Operate Chain of Trucks for Parcels Delivery

WASHINGTON, Jan. 2—The installation of motor truck parcel-post routes in various sections of the country, aggregating between 3000 and 4000 miles, is the plan of the Post Office Department. It is expected these routes will be in operation within the next 3 months. One chain of motor routes will extend from Portland, Me., to New Orleans. Another will cover much of a large stretch of territory in Ohio, Indiana, Illinois and West Virginia. On the Pacific Coast routes will be established between San Francisco and Sacramento, via Stockton and Fruitdale, a distance of 125 miles, and between Redlands and Los Angeles, via Ontario and Pomona, Cal., a distance of 76 miles.

The existing law does not provide for the employment of Government-owned motor trucks on rural delivery routes, nor does it require the rural carriers to use motor vehicles.

In the star route service, however, where the mail is carried under contract, a recent law permits the Post Office Department to designate the kind of vehicles to be employed, and in awarding new contracts the department will specify that motor trucks shall be employed on all routes where the roads are such as to admit of their use. These contracts are advertised for bidders, and where payment asked for the service is deemed to be excessive the department is authorized to provide Government-owned motor trucks and to employ drivers for the operation of these routes.

A further extension of the employment of Government-owned motor vehicles by its adoption for the parcel post service of the rural routes will be made whenever Congress enacts a law now pending for that purpose.

—

Expect Advance Rumely Profits Increase

LAPORTE, IND., Dec. 27—It is expected that profits of the Advance Rumely Co. for 1917 will be 30 to 50 per cent greater than in 1916 when the company earned $278,478. With the prospects of a record year for agricultural products throughout the country, the company is preparing for a bigger year than 1917, and in addition is trying to get government work to keep its plants up to their full capacity.

—

Fiat Absorbs Three Companies

TURIN, ITALY, Dec. 23—The Fiat Co. has absorbed three companies. They are: Ferriere Piemontesi Steel and Iron Foundries, capitalized at 9,000,000 liras; Officiene Gia Fili Diatto Railways and Trams Rolling Stock Works, capital 4,000,000 liras, and Industrie Metallurgiche Torino Steel and Iron Works, capital 4,000,000 liras.

Kliesrath Leaves Bosch— Buys Interest in Simms Co.

EAST ORANGE, N. J., Dec. 29—Victor W. Kliesrath, for many years chief engineer of Bosch Magneto Co., has acquired an interest in the Simms Magneto Co., East Orange, and after Jan. 1 will devote his entire time to the business in the capacity of consulting engineer. It is probable that new types of magnetos not made now by the Simms Magneto Co. will be added to complete a line of ignition equipment to meet every requirement. New types of interest will soon be announced.

—

A. C. Barber has been appointed division manager for the Willys-Overland Co. with headquarters in Moline, Ill. R. L. Butler is sales manager and has been transferred from Toledo to Moline.

—

C. R. Clough has been appointed sales manager of the Stephens Motor branch of the Moline Plow Co., with headquarters in Moline. He was formerly eastern district sales manager, and this position will be filled by his assistant, J. F. Hunter.

—

George M. Ellis and **W. C. Dudgeon** have joined preparatory classes for the ordnance department at Ann Arbor. Both were connected with the Campbell Ewald Advertising Agency. L. W. Chamberlain, of the Carl M. Green Advertising Agency, is planning to join them.

—

Ferris B. Fick, purchasing agent of the Saxon Motor Car Co., has resigned to become purchasing agent for Chalmers material at the Maxwell Motor Co., Detroit plant.

—

C. J. Pomeroy, formerly in charge of the operating department of the Seattle branch of the B. F. Goodrich Co., has received the commission of captain in the United States Army. He will be stationed at Camp Lewis.

—

Gregory Flynn, for seven years sales manager of the Rajah Auto Supply Co., Bloomfield, N. J., has been appointed assistant to the president of the Edward A. Cassidy Co., New York.

—

C. J. Elston, service manager of the Saxon Motor Car Co., Detroit, has resigned to become sales representative of the Asbestos & Rubber Works of America, New York.

—

C. T. Dunkle, formerly manager of the Columbus branch of the Willys-Overland Co., has organized a $100,000 company under the style Overland-Dunkle Co. to take over Overland sales in central Ohio territory.

—

C. J. Cunningham has been made service manager of the Detroit Weatherproof Body Co. For the past three years he has been working in the factory with this positien in view.

Men of the Industry

Changes in Personnel and Position

P. P. Hinckley has been transferred from the sales department of the Connecticut Telephone & Electric Co., Meriden, to the position of purchasing agent of the company.

—

Wetmore Hodges has been elected vice-president and general manager of the Haskelite Co., Grand Rapids.

—

A. W. Sayre has been appointed district manager of the Willard Storage Battery Co. factory branch at New York. He was formerly in charge of the Willard service station, Rochester, N. Y.

—

Edwin P. Jones has been made manager of the Brooklyn branch of the Firestone Tire & Rubber Co., to succeed H. A. Lane. Jones has been manufacturers' representative for several Western hardware concerns, and has also been connected with the Philadelphia branch of the Firestone organization.

—

R. M. Hernandez, for 10 years with the United States Tire Co. in the central States district, has been appointed central district manager of the Carlisle Cord Tire Co., Inc. His headquarters will be at Chicago.

—

Charles E. Stahl has been made assistant general manager of the Connecticut Telephone & Electric Co., Meriden. He will continue the direction of the sales department.

—

Raphael Semmes, vice-president of the Semmes Motor Co., Washington, has received a first lieutenant's commission in the Signal Corps. He will probably be attached to the non-flying division of the aviation section.

—

A. N. Pearson is district representative in the New England States for the Denby Motor Truck Co., and will have his headquarters in Boston.

—

Roy Coffeen has been made branch manager of the Willys-Overland, Inc., succeeding M. O. Bridgman who for the past 5 years has been branch manager.

—

G. G. Giese, St. Louis, secretary and manager of the Panama Rubber & Equipment Co., has joined the Quartermaster's Department.

—

Leonard Veith Passes Away

NEW YORK, Dec. 22—Leonard Veith, secretary of Asch & Co., died yesterday.

McMullen Goes West— To Represent Timken Co.

DETROIT, Dec. 31—George C. McMullen, assistant plant manager of the Metal Products plant of the Timken-Detroit Axle Co., has been obliged to leave Detroit due to the poor health of Mrs. McMullen. He will locate in or near Los Angeles, and will represent the Timken-Detroit Axle Co. and the Timken Roller Bearing Co. on the coast. The Detroit plant with which McMullen has been associated for the past two years has given him an indefinite leave of absence. Previous to the above-mentioned connection he was with the Crane Motor Car Co. of Bayonne, N. J., for five years.

—

Donald F. Whitaker, sales and advertising manager of the Detroit Truck Co., has resigned.

—

L. Berry, Chicago, has been transferred to St. Louis as manager of the Ahlberg Bearing Co. branch.

—

Robert Bron, formerly with the Union Electric Co., St. Louis, has been appointed manager of the Philadelphia storage battery service in that city.

—

L. A. Sumner, former general factory manager, is now assistant general manager of the Allen Co.

—

C. L. Allen has joined the Chevrolet Motor Co., having resigned as production manager of the Allen Motor Car Co.

—

G. E. Draw Mutual Motors Trustee

JACKSON, MICH., Nov. 13—G. E. Draw has become trustee for the Mutual Motors Co., which manufactures the Marion-Handley. He was formerly treasurer. An inventory is being taken and manufacturing has been stopped. The capitalization is $1,000,000, having 500,000 shares of common and 500,000 of preferred.

—

Oakland Gets 50 Freight Cars

PONTIAC, MICH., Dec. 26—The Oakland Motor Car Co. has obtained 50 new Northern Pacific freight cars for motor vehicle transportation. These are being loaded for immediate passage to Seattle and Portland. Each freight car will carry 5 vehicles.

—

Packard Starts Trucking Exchange

DETROIT, Dec. 26—The Packard Motor Car Co. has established a Detroit Trucking Exchange, to serve as a truck clearing house. Owners of trucks are listed, and when a company requires an additional truck the exchange is advised and obtains an idle truck. This service, which is performed without charge, will help relieve terminal and warehouse congestion, improve the freight situation and keep material moving.

—

L. E. Joels has been appointed works manager of the Duesenberg Motors Corp., New York. He occupied a similar position with the Packard company.

Digitized by Google

Studebaker Government Work Reaches $13,000,000 Mark

NEW YORK, Jan. 2—The Studebaker Corp. is understood to have orders for Government work amounting to $13,000,000 and it is stated that the consummation of these orders may operate to reduce the production of passenger cars to substantially below the 50,000 car mark reached in 1917. The Government work is for such products as escort wagons, water tank wagons, mine anchors and artillery wheels. Both the South Bend and Detroit plants will be utilized for this work.

—

Smith Adds to Directorate

CHICAGO, Jan. 2—The Smith Motor Truck Corp. has added the following men to its directorate: P. L. Coonley, vice-president Link Belt Co., Chicago; C. E. Danforth of Van Emburgh & Atterbury; W. R. Dawes, vice-president Central Trust Co., Chicago; O. J. Fehling, manager National Malleable Castings Co., Chicago; D. W. Figgis, president of the company; David R. Forgan, president National City Bank, Chicago, and C. B. Little; J. M. Hoyt, Central Bond & Mortgage Co., Chicago; J. L. Putnam, New York. It is stated that the company has marketed slightly more than 20,000 Smith Form-A-Truck units during the year.

—

New Upholstery Material

CHICAGO, Jan. 2—Wilson & Co., one of the largest packers and provisioners in the country, has been granted a patent on a new process of preparing curled hair for use in upholstery. The patent is No. 1,248,066. The new process is one by which curled hair is woven on burlap fabric. With the new product a piece of woven hair cut to dimensions, and of uniform thickness, is used in place of loose curled hair which heretofore has been used extensively. The new product eliminates difficulties with properly upholstering seat cushions and makes impossible any bunching of the hair after the cushion is completed.

—

Wisconsin Duplex to Have Oshkosh Plant

OSHKOSH, WIS., Dec. 31—The Wisconsin Duplex Automobile Co., which was organized a year ago with $500,000 capital to manufacture a quadruple-drive passenger and commercial car chassis, has selected Oshkosh, Wis., as the permanent location of its factory and offices. Early in the spring a large machine shop will be erected and the manufacture of chassis undertaken on a large scale. Until then the present experimental shops at Milwaukee will be continued for a regular output of a limited number of cars.

—

Changes in Capital

MILWAUKEE, Dec. 29—The W. S. Seaman Co., manufacturer of closed car bodies, has increased its capital stock from $50,000 to $150,000.

—

CLEVELAND, Dec. 28—The Hydraulic Pressed Steel Co. has increased its capitalization from $5,700,000 to $7,200,000.

—

SAGINAW, MICH., Dec. 27—The Erd Motor Co. has increased its capital stock from $100,000 to $250,000.

Ajax Co. Buys $2,000,000 Greenpoint Plot for Factory

NEW YORK, Dec. 31—The Ajax Rubber Co., Inc., has bought a $2,000,000 plot in Greenpoint, adjacent to the site of the State Barge Terminal, on which it expects to build a factory and warehouse. The property, which consists of several old brick and frame buildings on about 169 lots, has a 900-ft. frontage on the East River and Newtown Creek, and an average depth of 470 ft. The tenants of these buildings have been asked to vacate immediately, and the Ajax company will improve the site as soon as building conditions are favorable.

The plot, which is opposite Twenty-third Street, Manhattan, is known as the "Sugar House property," being formerly occupied by the American Sugar Refining Co. as a refinery, and later as a storage warehouse.

—

Cooper Union Adds Engine Course

NEW YORK, Jan. 2—A motor vehicle engineering course has been added to the other night classes at Cooper Union Institute. It will include classroom work and there will be an extensive laboratory course, covering testing materials and engine testing. The course is free and will be conducted by Ethelbert Favary.

—

Stanley Hall Dies

BOSTON, MASS., Jan. 3—Stanley Hall of the H. & H. Specialties Co., formerly manager of some of the big tire branches in New England, died here last week after a few months' illness. He was a director of the Bay State A. A. of Boston and active in the accessory trade.

New Companies Formed

Latest additions to ranks of Automotive Industries

St. Louis Aircraft Co. To Make 3 Airplanes Daily

ST. LOUIS, Dec. 31—The St. Louis Air Craft Co. has been organized here, and in a few weeks will begin the manufacture of three airplanes daily. The motors will be shipped here to be placed in the assembled machines.

The Air Craft Co. was organized under the direction of A. J. Seigel, president of the Huttig Sash & Door Co., a planing mill. The St. Louis Car Co. joined in the organization to manufacture metal parts and the airplanes will be assembled at its plant. A small amount of special shop construction is required by the Huttig Co., but for the most part wooden parts will be manufactured in existing planing mills.

—

Zelle Tractor Co. Organized

ST. LOUIS, Dec. 31—The Zelle Tractor Co. has been organized to manufacture a tractor designed by William C. Zelle, a local engineer. The tractor has a 33-in. clearance, which enables its use as a cultivator of growing crops. Zelle is president of the new company and several local insurance men and bankers are officers. The company offers to sell $1,000,000 of stock in $20 shares.

—

Wisconsin Co. to Sell Supplies

APPLETON, WIS., Dec. 29—The Bradford Co. has been organized to deal in motor cars, accessories and supplies, with a capital stock of $25,000. The incorporators are H. N. Bradford, Benjamin Wild and E. Wild Bradford.

—

Smith Form-A-Truck Co. Formed in Milwaukee

MILWAUKEE, Dec. 29—The Smith Form-A-Truck Co. has been incorporated with a capital of $10,000 by William F. Coerper, Walter Mayer and Ray E. Coerper.

—

To Rebuild Storage Batteries

CLEVELAND, Dec. 28—The Storage Battery Rebuilding Co. has been incorporated for $13,000 by Henry L. Beggs and Samuel L. Bowlus.

—

London Wholesaler Opens Here

NEW YORK, Jan. 2—S. Smith & Sons Motor Accessories, Ltd., London, has opened a buying office in New York at 154 Nassau Street, with J. H. Rose in charge. Smith & Sons, which was established in 1841, and has branches in South Africa, Australia, New Zealand, the Dutch East Indies and Siam, has been finding it difficult to secure goods in England because of the war. Its volume in 1917 was nearly $4,000,000. The office will be permanently retained here after the war.

—

New Company to Make Safety Device

PEORIA, ILL., Dec. 29—The Safety Signal Corp. has been incorporated with a capital stock of $200,000 by B. F. Hardesty, W. H. Kirk and H. O. Johnson. The company will manufacture a safety device for motor cars.

—

Canadian Carburetor Co. Organized

TORONTO, Dec. 20—The (British) Young High-Velocity Carburetor Co., Ltd., has been incorporated with a capital of $250,000 by Henry H. Davis, Edward H. Brower, Lawrence A. Landriau and others. The company will manufacture carbureters, automobile accessories and machinery.

—

To Manufacture Bovey Heaters

CHICAGO, Jan. 2—The Bovey Automobile Heater Co. has been incorporated with a capital of $30,000 by Thomas Bovey, Sidney J. Bovey and Frank Thomason.

—

Engineering Corp. to Solve Truck Problems

CHICAGO, Dec. 26—The Engineering & Sales Corp., 122 South Michigan Avenue, Chicago, has taken over the engineering problems and supervision of purchases of the Oklahoma Auto Mfg. Co., Muskogee, Okla., and of the Mutual Truck Co., Sullivan, Ind.

—

Dividends Declared

BUFFALO, Jan. 2—The Curtiss Aeroplane & Motors Corp. has declared a semi-annual dividend of 3½ per cent on preferred stock, payable Jan. 15, to stock of record Jan. 2.

—

CLEVELAND, Dec. 27—The National Tool Co. has declared the regular quarterly and the usual extra dividend on common stock, together with 3 per cent interest and the regular quarterly dividend on preferred, all payable Jan. 2 to stock of record Dec. 28.

—

SPRINGFIELD, OHIO, Dec. 29—The Westcott Motor Car Co. has declared the regular quarterly dividend on the 7 per cent preferred stock, payable to stock of record Dec. 31.

—

PITTSBURGH, Jan. 2—The Westinghouse Electric & Mfg. Co. has declared a regular quarterly dividend of 1¾ per cent on common, payable Jan. 31 to stock of record Dec. 31, and a dividend of 20 per cent in stock payable Jan. 15 to stock of record Dec. 31.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

United States Motor Truck Plans to Triple Output

COVINGTON, OHIO, Dec. 28—Officers and department heads of the United States Motor Truck Co., Cincinnati, gave a dinner at the Industrial Club in honor of F. J. Alvin, general manager of the company. The officers pledged their determination to triple the output during the next year.

Those present included: R. C. Stewart, president of the company; R. S. Stewart, vice-president; F. J. Alvin, E. S. Lee, Jr.; E. C. Shumard, W. E. Dugan, E. A. Haskins, F. A. Trinkle, C. E. Hoover, William Lally, Fred Geiger, A. C. Durant, A. O. Fenning, H. W. Gillespie, E. B. Chamberlain, O. W. Williams, H. Z. Yeager, T. W. Semler, Walter Walkinghorst and Ralph H. Jones.

—

Haskelite May Use United Truck Building

GRAND RAPIDS, Jan. 2—The Haskelite Co., which manufactures veneer parts for airplanes, is starting work on its new plant. Pending its completion one of the new buildings of the United Motor Truck Co. will probably be used for experimental work in the making of airplane bodies.

—

Studebaker to Build New Factory

DETROIT, Dec. 27—The Studebaker Corp. has secured a building permit for a 4-story brick and steel factory 325 x 51. The cost will be approximately $150,000.

—

Indiana Truck Co. Plans Expansion

MARION, IND., Dec. 31—The Indiana Truck Co. will enlarge its plant to provide for a Government contract for 500 Liberty trucks.

—

American Forge to Build Heat Treating Plant

CANTON, O., Jan. 2—The American Forge & Machine Co., Canton, Ohio, is erecting a steel building 40 x 100 as a heat treating department. The building will be equipped with car type furnaces, heat receiving instruments and quenching tanks, thus insuring the scientific treatment of all forgings. Testing machines of various types will be installed.

—

One-Wheel Trucks in Market Jan. 3

ST. LOUIS, Dec. 31—The One-Wheel Truck Co. announces that first deliveries will begin Jan. 10. On that date three of the novel motors will come out of the shop. The first will go to the Anheuser-Busch Brewing Association.

Industrial Review of the Week

A Summary of Major Developments in Other Fields

COAL SITUATION IMPROVING

The consumption of anthracite has somewhat decreased during the past week. This has been due almost entirely to moderation of weather conditions, resulting in a less insistent demand for domestic fuel. The railroads have also by a strenuous cleaning up of the congested conditions resulting from the great snow storm of early December been able to move a slightly greater tonnage than during the past two or three weeks. The efforts of the anthracite operators to induce the mine workers to produce a maximum tonnage have been reinforced by admonitions from various ecclesiastics high in the Roman church, urging the miners to labor to their maximum capacity even on Sunday and other church days, excepting only Christmas and New Year's Day. It is rumored also that the period of labor during the present war may be extended from eight to nine hours per day. All of these circumstances combine to render the situation less strenuous than it has been in the recent past. On the other hand, car supplies to the mines and movement all-rail, particularly to New England points, have been poor, and some suffering has resulted from a lack of adequate fuel supply. It is hoped that the use of government locomotives, as well as those diverted to the East from points further west, will tend still more strongly to relieve the present situation.

The situation in bituminous coal is apparently but little less strenuous than formerly, the chief factor tending to relieve the situation being milder weather than formerly prevailed. On the other hand, there are certain symptoms which would indicate that the scarcity of domestic fuel particularly was not as great as was believed. Among these indications are the unwillingness of certain consumers who complained loudly that they were "freezing" to pay the contract price for coal which had been commandeered to meet their needs. The distribution of a considerable tonnage of coal intended for Lake shipment did much to relieve immediate fuel needs in Ohio and lower Lake territory generally. On the other hand, such manufacturing districts as Michigan and New England are extremely short of coal supplies, and unless a considerable tonnage is received shortly many manufacturing plants and public utilities will doubtless be required to close down, at least temporarily. A strong sentiment prevails which would favor the compulsory shutting down of unessential industries, such as the manufacture of musical instruments, and the like. This would not only relieve a certain amount of traffic in raw materials and finished product, but would tend also to set free a certain amount of labor which might be more advantageously used in other pursuits. Proper priority orders will doubtless accomplish this result. Already many cities have adopted "lightless nights," this term being applied to the burning of electric signs and similar advertising illumination. In some places also apartment house owners have adopted stringent measures to reduce the consumption of coal for heating purposes, while curtailment of street and interurban electric lines and abandoning of many passenger trains on various roads which were more or less superfluous, have all done much to conserve slender stocks of fuel. Complaints of shortage in bituminous coal are most pronounced among steam users, while the domestic consumers appear to be, if anything, better taken care of. It is apparent thus that although the production and receipt of steam coal is at least equal to that of last year, and in many cases far greater, the manufactories of the country are running at much higher capacity than was the case a year ago. —*Coal Age.*

A New Service

¶ *Herewith* AUTOMOTIVE INDUSTRIES *supplies for the benefit of its readers a general summary of important developments in other fields of business. This is rendered possible by the editorial co-operation of leading industrial publications which are recognized authorities.*

By compressing the general industrial situation into this form we hope to give our readers a clear and comprehensive idea of up-to-the-minute developments which they could otherwise secure only with considerable expenditure of time and effort.

CLEVELAND ORE PRODUCERS OBJECT TO CONTRACT REVISIONS

The expected announcement by the President that iron and steel prices would remain in effect for three months longer was made on Dec. 28. With it came the proviso, agreed to at a meeting of steel manufacturers and the War Industries Board held the same day, that on contracts made in the next three months prices would be revised on deliveries after April 1 to conform to any changes that might become effective on that date.

Iron ore producers at Cleveland are emphatic in objecting to the action taken as to the revision of contracts. Representing an industry in which contracts have always been made running 12 months ahead, they are opposed to making ore sales subject to a possible reduction in price. Pig iron soared far out of range with the ore prices of 1917, and the ore trade argues that for it an advance is in order now rather than a possible reduction.

The prospect of orders for 100,000 cars that comes with Government control of railroads is not unwelcome to equipment companies, but with the steel trade the practical question is what tonnage of plates can be spared for car building. The shipbuilding program will absorb more steel later in the year, but new plate capacity is nearing completion and shipyards are not yet organized to take the present plate mill output in full.

Surprisingly large additions to the country's steel making capacity are shown by the statistics for 1917. In the year 97 new open-hearth furnaces, some of which will be operated duplexing, were completed, capable of an output of 4,326,500 tons of ingots per year. Of this total 1,220,000 tons is furnished by the Steel Corporation. In 1916, previously the record year, the new capacity added was 4,205,000 tons.

Fourteen new blast furnaces were blown in in 1917, with annual capacity of 2,520,000 tons, against only five furnaces in 1916 with capacity of 800,000 tons.

In the face of all this new construction is the fact that pig iron production in 1917, estimating that of December at 3,000,000 tons, was but 38,700,000 tons, or 735,000 tons less than in 1916. Coke was the limiting factor, as has been said over and over.

At the same time, by drawing on pig iron stocks and by a larger use of scrap, steel works produced about 42,400,000 tons of ingots last year, or 1,000,000 tons more than in 1916, making 1917 the high record year.

The 9000 railroad cars for Italy are about placed. The bulk if not all is likely to go to the Standard Steel Car Co. and the American Car & Foundry Co. Both have uncompleted Russian car orders and could utilize some of the steel on hand and under orders.

Manufacturing consumers end the year as a rule with fair stocks of material. In many general lines activity has tapered off, and with Government price control there has not been the incentive to seek maximum protection through contracts. Now that Washington stipulates that price revision on deliveries after March 31 will be in order, the average buyer may show more interest. Meanwhile his output has been subnormal because of transportation delays and labor shortage, and this fact accounts for the smaller stocks he has been satisfied to carry.

In northern Ohio, in contrast with some other districts, there is active demand for pig iron, one inquiry from Erie, Pa., representing Government work, being for 3000 tons of basic iron per month for a year, beginning with March.—*Iron Age.*

Open Bids for Postal Trucks

WASHINGTON, Jan. 2—The post-office department will open bids Jan. 10, at 2 o'clock p. m., for not to exceed fifty motor gasoline motor trucks of from 1 to 1½-ton capacity, equipped as follows:

Screen body, screens front and rear; front screens, collapsible gate type; rear screens, hinged doors opening outward, with proper lock; body built out over wheels with wells in front to accommodate wheels; screens to be carried up from edge of flare boards to roof, properly supported; tires, 36 by 6, pneumatic cord, extra tire mounted on rim; tire rack, complete; headlight lenses to be of a type meeting requirements of various State laws; each car equipped with full set of chains and the customary tool equipment; bodies to be painted green, with gold lettering and red running gear.

—

Torbensen Axle Co. Insures Employees

CLEVELAND, Dec. 28—The Torbensen Axle Co. gave each of its 500 employees a certificate of insurance as a Christmas gift. Those who have entered the service of the company since July 1, 1917, are insured for $250, this amount to be raised to $500 upon completion of 6 months' service. Those who have been with the company for more than a year are insured for $600, with an increase of $100 for each additional year of service until a maximum of $1,500 has been provided. This insurance was in force from noon of Dec. 24, and does not interfere with the Workman's Compensation as provided by the Ohio State law.

—

Model Factory for Fan Belts

ENDICOTT, PA., Dec. 31—Walter L. Johnson, manufacturer of fan belts, will open a model factory here. The building will be 150 x 60, and more than 3,000,000 fan belts will be manufactured in it during 1918.

Calendar

ASSOCIATIONS

Jan. 3-4—New York Automotive Electric Assn. meeting.
Jan. 7-8—New York, National Automobile Dealers' Assn. directors' meeting with vice-presidents from Eastern States.
Feb. 4-7 — St. Louis, American Road Builders' Assn. Convention.

SHOWS

January — Kalamazoo, Mich., Kalamazoo Automobile Dealers' Assn., Armory.

More Casting—Less Forging

High Cost of Dies and Materials Having Influence on Relative Standing of Forgings, Malleable Iron and Steel Castings

By J. Edward Schipper

THE marked trend toward the more extended use of forgings for brackets, axle parts, etc., has been somewhat checked by the abnormally high prices asked for forgings at the present time. The result of this condition has been a temporary tendency toward an increased use of malleables. It is not probable, however that this tendency is any indication of a permanent condition. Manufacturers have been forced, in some instances, to change from forgings to malleables and in a few instances from malleable to steel castings, simply because of the difficulty in obtaining delivery of certain parts.

Further than this, in view of the present prices of forgings, malleables are being used for some parts where the size is a matter of convenience rather than of structural strength. In a great many trucks which ordinarily would employ forgings, practically all of the frame brackets, spring hangers, motor brackets, etc., are of malleable iron. All parts which are in tension, and particularly those which are under shock, such as shackle links, are made from forgings if possible, and if not, from steel castings.

Forgings the Natural Choice

For the vital parts of all trucks and passenger cars forgings will continue to be used. This refers particularly to such parts as axle centers, steering connections, propeller shaft parts, etc. It is this condition which has put a check for the time being to the big trend toward forgings and stampings, but as soon as the war is over, and conditions are relieved, it is certain that the forgings and stampings will once again come into their own.

The use of forgings, where commercially possible, is a practice which engineers come to whether they go at the matter scientifically or simply by practical results. In the language of one of the prominent tractor engineers, "We use malleable, cast steel and drop forgings for different parts of trucks and tractors. If malleable castings do not stand up, we use cast steel and when cast steel does not give service, we use forgings." This is a rough and ready way of expressing the thought that forgings are not only arrived at by scientific calculation, but also by the results obtained in every-day practice.

It is not an easy matter to classify parts in such a way that by referring to a tabulation you can tell whether it is best practice to use a forging, a casting or a malleable. The question of machining and the question of strength in relation to size, and in some instances the question of weight, always must be considered. Nevertheless, practical experience affords a rough and ready classification, based on the thought that experience indicates clearly the desirability of avoiding the use of cast steel or malleable iron for any parts where the duty is in any way severe.

Many Fear Castings

There are many engineers who fear castings because they are treacherous. It is almost impossible to tell, unless they are machined all over, whether they are sound or not, and steel castings are often the worst offenders in this respect. For such brackets as the rear spring frame brackets and the front spring front end brackets, cast steel or malleable iron is fairly satisfactory from the standpoint of ability to endure in service, although the production losses, due to defective castings, are higher than they should be.

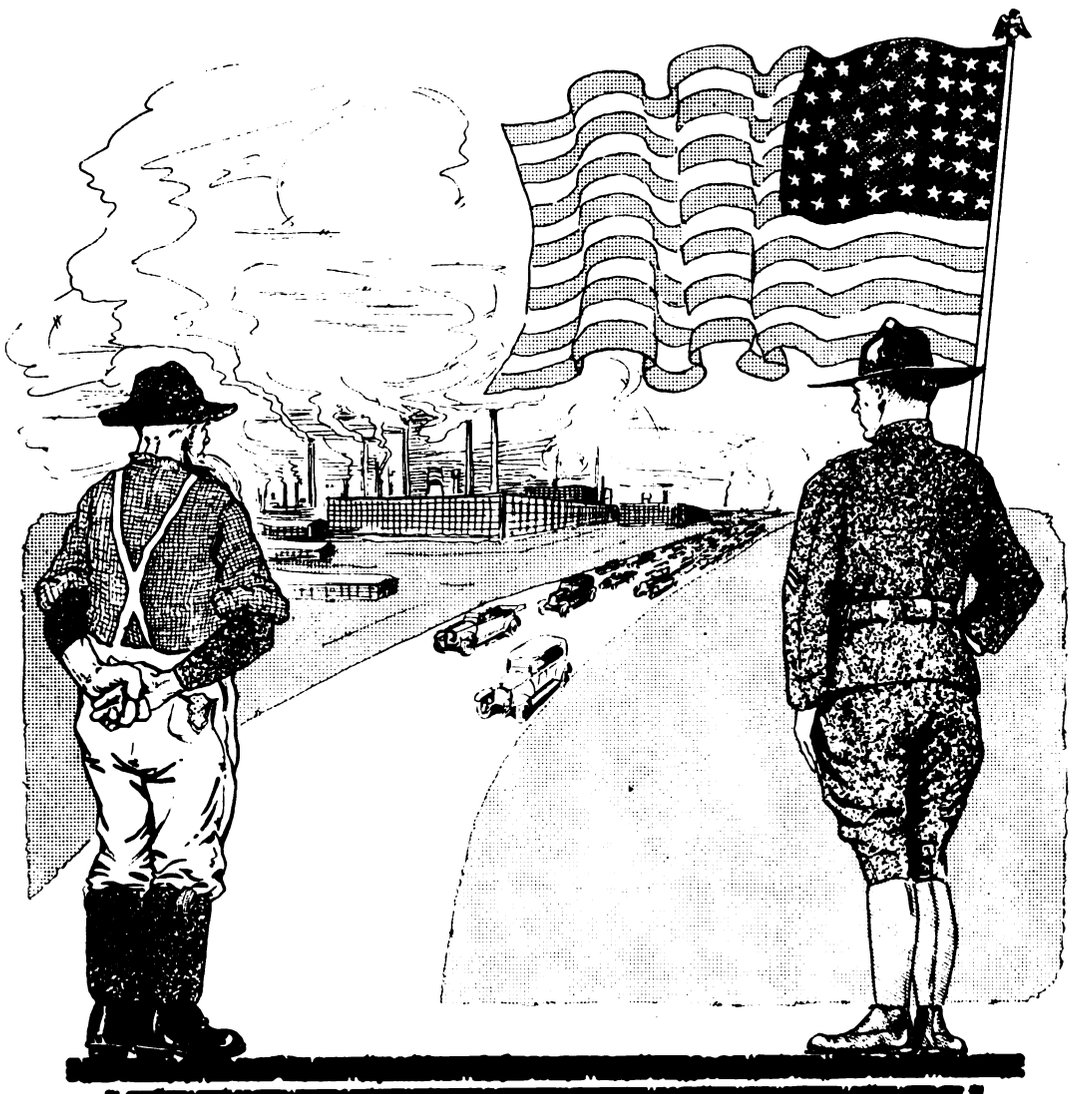
It is true that steel castings are better than they were three years ago, but there is a serious question as to whether the progress in casting has kept pace with progress in design. In other words, the duties required of the parts which have been made of castings in the past have been so increased by the requirement of lightness and other factors necessitating greater unit strength, that steel castings cannot now be used for many of these parts.

Production Losses High

Many engineers feel that there is a strong tendency to get away, as far as possible, from the use of castings for anything except housings or short, stubby brackets, as, where parts can be made of either forgings or stampings, they are much more certain to stand up in service and to be flawless when first made, thus cutting down the production losses. In fact, in estimating the costs on the comparative basis of making certain small parts from castings or forgings, one of the points which must be considered in order to arrive at a fair conclusion is whether or not the production loss, due to defective castings, will not more than overcome a difference in the first cost of the forging. The regrettable part of the losses in castings is that the flaw may not be discovered until several machine operations have been completed, so that losses include not only the material itself, but also the labor and machinery time costs as well.

Rules for Selection

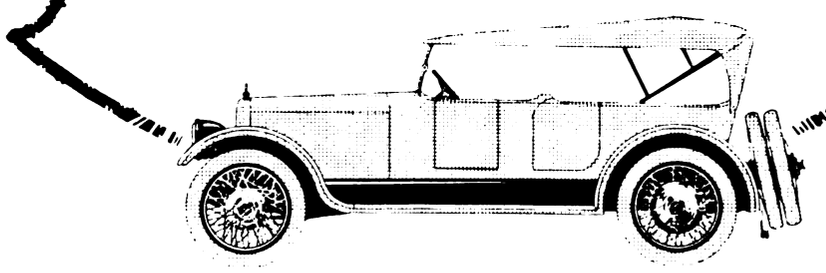
A very prominent engineer in charge of motor truck construction in this country states that the following rules guide him in selecting cast steel, malleable and drop forgings for small brackets, axle parts, etc.:



1—Cast steel is used for more important structural parts that cannot be forged. It must be made fairly heavy to allow for segregation in the castings, blow holes, etc. It should really only be used for complicated pieces.

2—Drop forgings should be used where very great strength is required, with lightness.

3—Malleable iron should be used for unimportant structural parts, such as spacers, packing pieces and the like; parts where cast iron itself would probably be strong enough as regards the actual work to be done, but not strong enough to bear transportation and rough handling.



4—In general, it is a very wise rule to use forgings as much as possible, as, after the first cost of dies, they are usually found to be cheaper, much more homogeneous.

National

TWELVE CYLINDER CARS

ANSWERING THE NEED *of* TODAY

THE nation-wide urge for basic soundness in economy and service is nowhere answered more sincerely than in this new twelve-cylinder National Sedan.

By perfection of material and careful construction it has been given an endurance and low operating cost that bring unusually high return on the owner's investment.

To this true economy is added its superiority as an all-season vehicle.

Luxurious and dignified as a limousine, it is equipped with studied reference to the complete utility essential in an all-purpose car.

The adoption of the smooth, twelve-cylinder, airplane-type motor has given ample power for all tasks—it is as able upon hills and country roads as upon smooth city streets.

Ease and simplicity of operation, constant reliability, roominess—it seats seven passengers—and its unfailing comfort have made it a favorite with women as with men.

This new National Sedan affords the full scope of automobile use—comfortable travel in all seasons, under all weathers and over all roads.

Its conversion from a closed car to an open one is instant and easy and in either model the beauty of its lines is preserved.

For the purchaser it offers that long term of service that is the final element in determining true value and economy—to the dealer it brings the advantage that accompanies year 'round sales opportunities.

"There doubtless are other good bearing bronzes, but I *know* Non-Gran is good and I *know* Non-Gran is uniform."

The man and engineer who spoke those words is known to every Automotive Engineer not only of this Country but of the entire World. You know him, as does everyone else, as easily one of the first five Automotive Engineers of America. In those few words hasn't this man expressed the majority opinion of the entire American Automotive Industry?

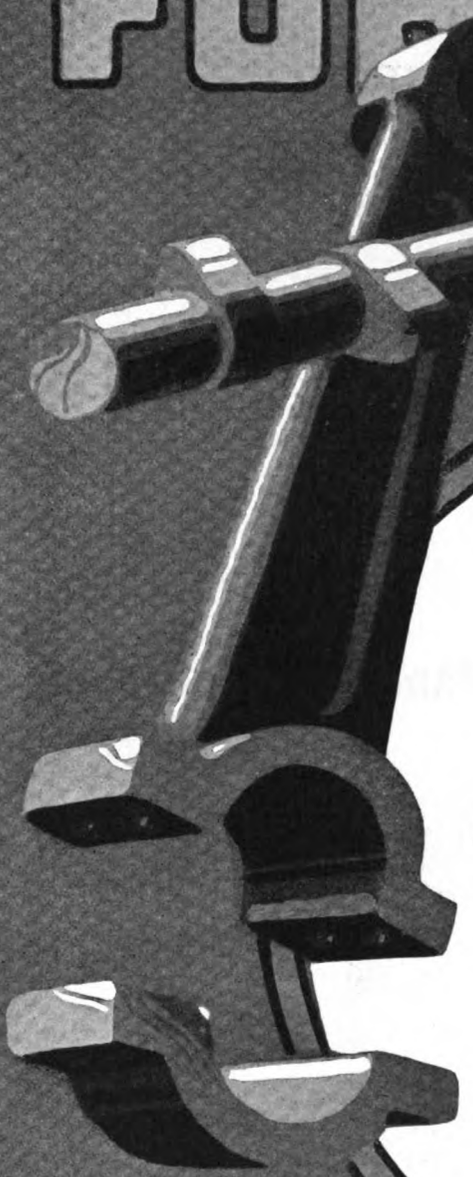
Over 250,000 Now in Use as Standard Equipment

The Waltham Automobile Clock



has two mainsprings and is stoutly and scientifically built to resist the shocks of road travel and the extremes of temperature. It is the **only** clock so built and so adjusted. It tells the right time. It is splendidly durable.

In appearance it conforms with the luxurious cars that use it. A red signal on the dial shows when the clock needs winding. The presence of a Waltham in a car has become an index that points to the car's class.

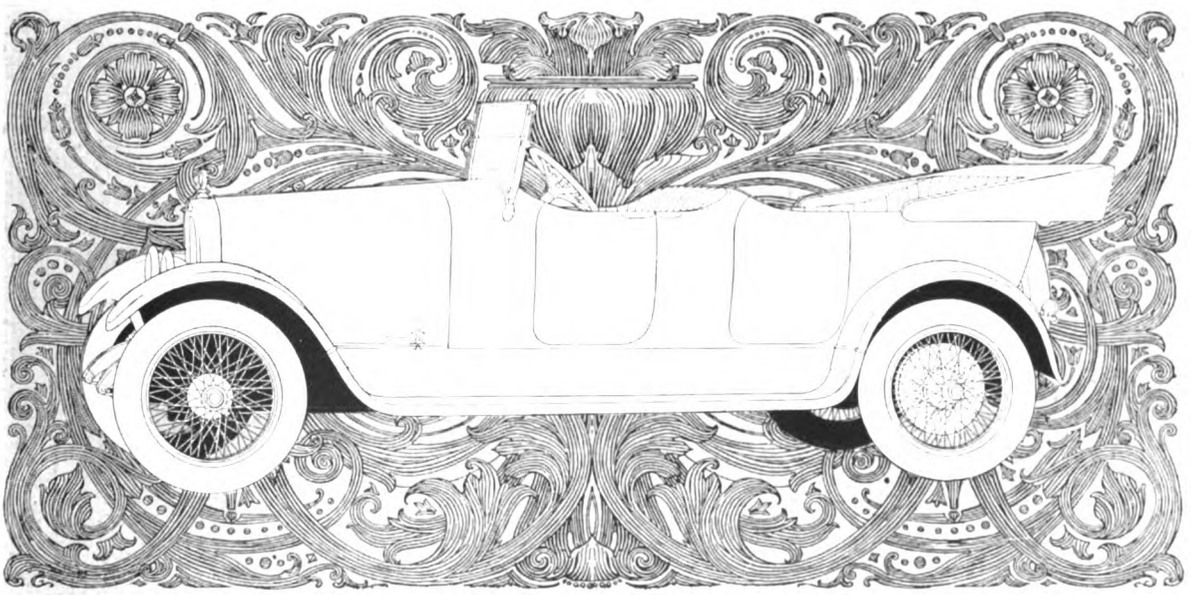
Present The



NEW SERIES

MARMON 34

To Be Seen At The Principal Motor Shows

THE distinguishable differences between this and the preceding series are the wider seats and the deeper sides. There are, in addition, numerous refinements not readily perceptible but none the less effectual in making this celebrated car even more comfortable, luxurious and convenient than before.

On the following page—an invitation to dealers.

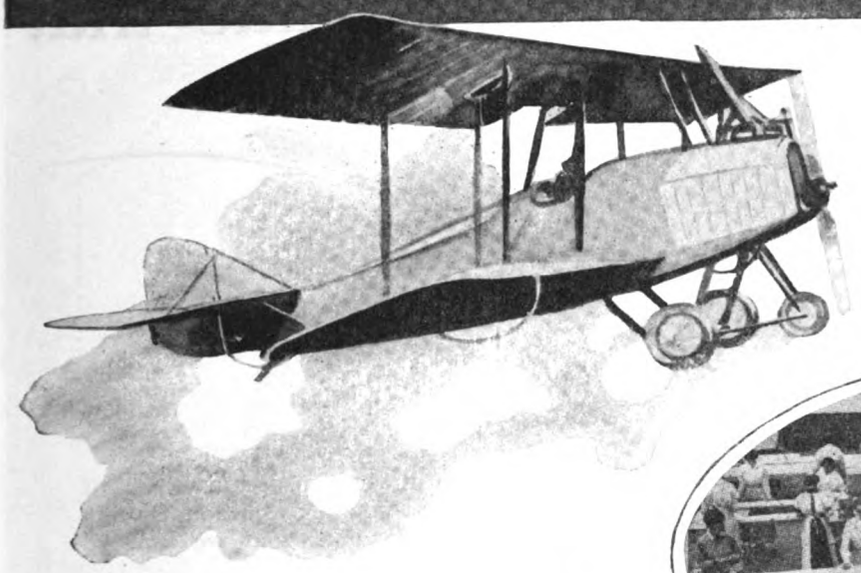
MARMON 34

Advanced Engineering

An Invitation To All Automobile Dealers Who Will Attend The Motor Shows.

THE Marmon Exhibit will include four models of the new series Marmon 34. They will comprise not only interesting attractions from the car buyer's standpoint, but will constitute a factor of first import to dealers.

There will be shown the Marmon open cars that are a half-ton lighter than those of equal size and power, and the Marmon enclosed cars that weigh less than open cars of competitive build.



The Marmon Chassis will be found to be the same for all types of bodies-wheelbase 136 inches.

May we not hope to have the pleasure of showing you the new Marmon excellencies as a matter of interest to you and of pride with us?

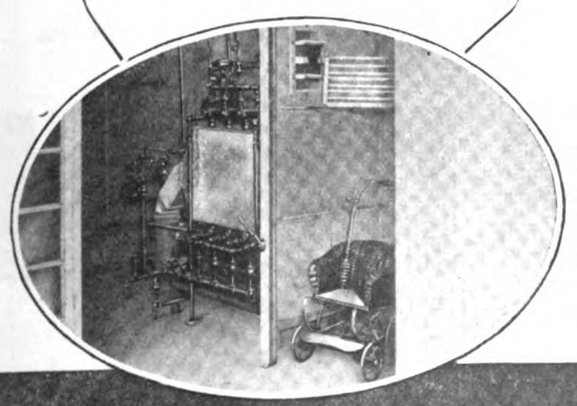
Weather-Proofing the Airplane

Here is a new—almost an unknown—field. The airplane presents not only difficult, but most exacting requirements. Varnishes, Japans and Enamels, on airplane parts, are called upon to withstand the most extraordinary changes in temperature, from summer heat to winter cold in a few minutes; sudden changes from arid dryness to heavy moisture; tremendous winds, unusual strains in every conceivable direction.

Bring Your Finishing Troubles to Us.

We maintain what we call a "Better-the-Finish" Laboratory, which is devoted to the thorough study of individual finishing problems put up to us by various manufacturers.



Perhaps we can save you time and money, and also improve the appearance and wearing qualities of the finish on your products.

Motor Cars, Trucks, Trailers, Tractors, Motorboats, Airplanes, and their parts and accessories are receiving our particular attention.

It will cost you nothing to get the benefit of our special knowledge and experience in this line. And it may save you time and money.

Manufacturers handling government work should bear in mind that our experience in co-operating with firms handling similar work is at their disposal.

Automatic Drying Ovens of a type suited to airplane wings, fusilage, auto bodies, etc.

HILO

Varnishes—Enamels—Japans

Our "Better-the-Finish" Laboratory is co-operating with the Society of Automotive Engineers in developing Standard Specifications for Airplane Varnishes, Baking Japans, and Colored Enamels.

Let us co-operate with you in the solution of your finishing problems. Write for our Bulletin No. 1 on Black Enamels and Japans. It contains information of value to you whether you use our material or not.

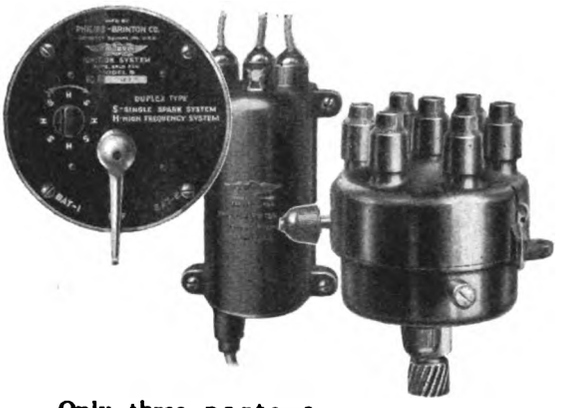
"—and with the battery so weak that it wouldn't blow the horn, we made that hill on high."

THE old horn wouldn't even "squawk," but with our new Philbrin Duplex Ignition System the motor never missed once, and we breezed right up over the top.



Philbrin Duplex Ignition combines in one system, a main or Single Spark System, and a secondary or High Frequency System. For the ordinary steady running the Single Spark System is used. Its new patented Contact Maker and Condenser build up an extremely high potential, provide for an instantaneous break, and the intensely hot spark which results **fires exceedingly lean mixtures**—saves gas—and gives you added power and flexibility, with greatly increased economy, both of gas and current.

But for abnormal conditions, when you are troubled with poor gas, fouled spark plugs, cold cylinders, or poor carburetion, just turn the switch to "H," and the resulting stream of hot, intense sparks from the High Frequency System relieves all ignition troubles—**spurs the motor to super-service.** You can easily take the steepest grades, or slide along on high as smoothly at four miles as at forty.

Philbrin Duplex Ignition is more dependable than any single system could possibly be, and each separate system or unit is also vastly superior in performance to all other systems.

Philbrin Duplex is the last word in Ignition, and Philbrin Systems are made for any car for replacement of single spark systems, magnetos, and also for first installation.

Dealers: Write for our exclusive sales proposition. Valuable territory is still open.

Only three parts—a combined switch and magnetic interrupter, a coil, and a distributer

CASE SIX

Three Fine Models

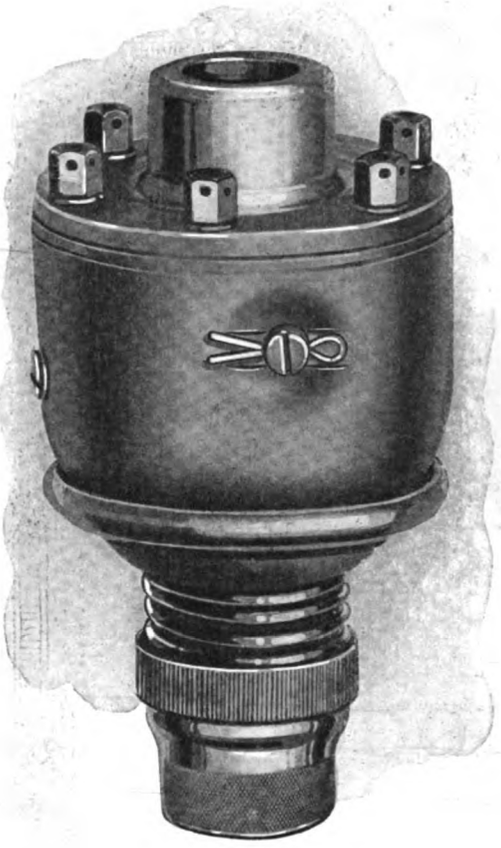
The New Case Offering

EACH is the latest creation—each a pattern to set new standards. Such are the New Case Sixes—in a Touring Car, a Sport Model, a Sedan. Each combines beauty and mechanical excellence. Each typifies new-day ways of manufacture. Each embodies the Case idea of including all the wanted features. An expert has wisely named this the "All-Feature" Car.

The New Case Six is our latest triumph. Case Engineers have surpassed all previous efforts. The trade confirms it. And the public confirms it.

This New Case Six is the best, the finest, the handsomest car we ever built. In dozens of ways, experience has directed our designers and builders. This is a speedier, more powerful car. It is easier to drive, more comfortable to ride in. It has grace and beauty. It has appointments rarely found in cars of equal price. We offer the open models of this new car for $1875. Men say they would bring more. The brisk demand indicates wide appreciation.

To a few dealers who command a clientele of motor-wise buyers, we have an attractive proposition to offer. *If you are interested, please advise.*



Family Model, a 7-Passenger Touring Car, color dark blue, $1875; Sport Model for four people, color periscope green, $1875; All-Seasons Model, Springfield Type, for 7 or 5 people, color dark blue, $2375.

J. I. CASE T. M. CO., INC., 204 Liberty St., Racine, Wis.

(*Founded 1842*)

The New Case Six in three models will be exhibited at the New York and Chicago Shows

KEEP YOUR CAR YOUNG 1918

Seven
Auto
Necessities

with

JOHNSON'S AUTO PRODUCTS

Freeze-Proof
Carbon Remover
Prepared Wax
Liquid and Paste
Stop-Squeak Oil
Radiator Cement
Cleaner
Auto-Lak
Black-Lac

OF THE four and a quarter million cars in service, 95% are cared for by owners themselves. And a large percentage of these owners use some of the Johnson Products shown on the following pages.

These products are auto necessities—every one of them. If you try to get along without them, you not only sacrifice something of pleasure and pride, but you also pay more for the neglect.

Here's a good New Year's Resolution; Resolve to Keep Your Car Young. Keep it bright and shining on the outside and keep the motor quiet, powerful and snappy. A little care will increase its market value 15% to 25%.

Try these products—all of them—at the first opportunity. Order direct from us if you can't buy locally. Write for our free booklet, "KEEP YOUR CAR YOUNG".

To The Trade

Hundreds of jobbers and thousands of dealers are sharing in the Johnson profits. Don't invest your capital in unknown brands when you can get these sure selling, fast moving Johnson products.

We deliver the customers to you. Will you deliver the goods to them? Get our proposition.

Prevents Frozen Radiators

Does Not Evaporate

JOHNSON'S FREEZE-PROOF

Johnson's Freeze-Proof is put up in packages containing 6½ lbs. net which retail at $1.50 each in the U. S. A. One package will protect a Ford from freezing at 5° below zero. For larger cars use two packages to protect to 5° below zero, and three packages to protect to 20° below zero.

THE only way you can be positive that your radiator won't freeze up in winter is to use a non-evaporating, anti-freeze preparation. The present high price of Alcohol—its low boiling point—and quick evaporation make it impractical. Besides, you are asked to conserve the supply of Alcohol for use in explosives.

Does Not Evaporate

Johnson's Freeze-Proof does not evaporate so one application is sufficient for the whole winter unless the solution is weakened by leakage of the radiator or hose connections, through the overflow pipe, or by boiling over.

Absolutely Harmless

Johnson's Freeze-Proof contains no oil and does not interfere with the cooling system. It will not injure rubber, cloth, packing or metal of any kind. It does not rust or corrode any metal. Johnson's Freeze-Proof is economical and easy to use and it raises the boiling point of water 12° to 25°.

Johnson's Freeze-Proof should be used wherever you wish to prevent water from freezing—in automobiles, gas engines, tractors, electro-lighting and heating plants, traction companies, etc. One box will prevent 3½ gallons of water from freezing at 5° below zero. For lower temperatures increase the proportions of Freeze-Proof.

S. C. JOHNSON & SON, Dept. A, RACINE, WIS.

Increases Power

Saves Gasoline

JOHNSON'S CARBON REMOVER

REGULAR use of Johnson's Carbon Remover—once every 500 or 1000 miles—will cure 80% of your engine troubles, and keep the engine right up to the top notch of efficiency all the time. It will increase your power, save 12% to 25% of the gasoline and reduce maintenance expense.

Johnson's Carbon Remover puts new life in your engine. It cleans out carbon, stops knocking and pounding, gives more power on the hills, improves the "pick-up" and restores the original "pep" and smoothness.

With proper carbon removal, you'll have better compression and less valve grinding, less ignition trouble and lower oil consumption. Johnson's Carbon Remover is easier, quicker, less expensive and more effective than any other method—more effective because it is thorough and because you won't neglect to use it often after the first trial.

Do It Yourself — No Trouble

Simply pour an ounce of Johnson's Carbon Remover into each cylinder in the evening. Over night it soaks into the accumulated carbon and leaves it a soft inflammable mass. When you start your engine the next morning this mass burns, pulverizes and is blown out with the exhaust in powder form.

S. C. JOHNSON & SON, Dept. A, RACINE, WIS.

Preserves the Finish

Keeps Cars New

JOHNSON'S PREPARED WAX
Liquid and Paste

Prepared Wax Liquid

Quarts	$1.40
Pints	.75
Half-pints	.50

CLEANER

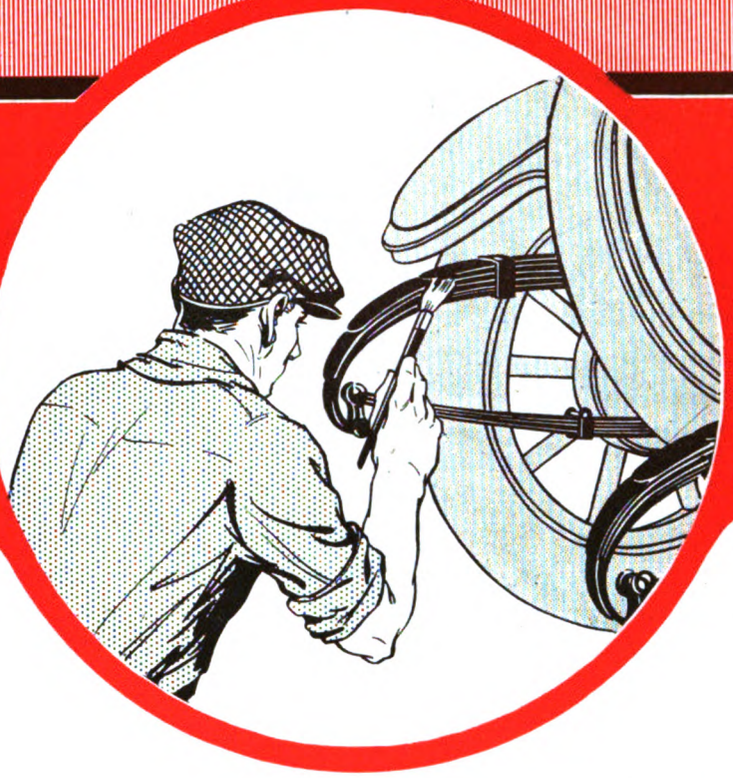
Auto Size (8 oz. net) $ .35

If your dealer cannot supply you with Johnson's Prepared Wax and Cleaner we will prepay the express to all points in the U. S. east of the Rockies.

YOU can't thoroughly enjoy your car unless you are proud of it and you can't be proud of it unless it always looks clean and bright. This is a difficult problem when you consider the severe exposure—sun, wind, rain, snow, mud, dust—to which a car is constantly subjected. No ordinary furniture polish will do.

But Johnson's Prepared Wax is no ordinary polish. In paste form it has for years been the standard preparation for using on fine furniture, pianos and hardwood floors. Now the same preparation in liquid is coming into its own as the standard of automobile polishes.

Johnson's Prepared Wax Liquid is very easy to apply and polish—very little rubbing is necessary. Apply it with cloth, brush or spray. Quickly removes road oil. It preserves the varnish and protects it from the weather, adding years to its life and beauty. It covers up mars and scratches—prevents checking—sheds water and is absolutely dust-proof. A wax polish stays clean longest.



JOHNSON'S CLEANER

If your car is covered with spots and stains which washing will not remove, clean it with Johnson's Cleaner before waxing. Johnson's Cleaner really cleans. It removes spots, stains, tar, alkali, etc. Even those spots that are ground in—mud freckles—and surface scratches you thought were permanent—will dissappear like magic under Johnson's Cleaner.

S. C. JOHNSON & SON, Dept. A. RACINE, WIS.

Makes Springs Lively

Stops Rust and Squeaks

JOHNSON'S STOP-SQUEAK OIL

STOPPING the squeaks is only one purpose of Johnson's Stop Squeak Oil. Its chief use is to make cars ride easily—to make them float instead of bump and jolt along. Its chief characteristic is its ability to penetrate—to seep in between the spring leaves as kerosene permeates a lamp-wick. It penetrates and still it acts as a heavy-bodied lubricant.

You don't have to jack up the car and pry the spring leaves apart to apply this oil. Paint it on the sides of the springs with a brush, or squirt it on with an oil can. It goes right to the spot where it is needed and stays there.

Stop-Squeak Oil prevents rust between the spring leaves. It makes them slide easily on one another so that every jolt and jar is absorbed by the springs. Reduces liability of spring breakage.

You'll never realize how sensitive and effective your springs are until you have them properly lubricated. You'll never realize what an easy riding car you have until then.

Johnson's Stop-Squeak Oil will remove squeaks of all kinds—in springs, shackle bolts, body fenders, top, etc. Just locate the squeak and touch it with Johnson's Stop-Squeak Oil.

S. C. JOHNSON & SON, Dept. A RACINE, WIS.

Quarts ..... **$ .85**
Pints ..... **.50**

Write for our booklet entitled **"Keep Your Car Young"**—we will send it to you free and postpaid. The information in this booklet will enable you to greatly improve the appearance and performance of your car.

Mends Leaky Radiators

No Tools Required

JOHNSON'S RADIATOR CEMENT

A NEW and efficient way of mending leaky radiators is with Johnson's Radiator Cement. It is quicker more economical and more satisfactory than any other method.

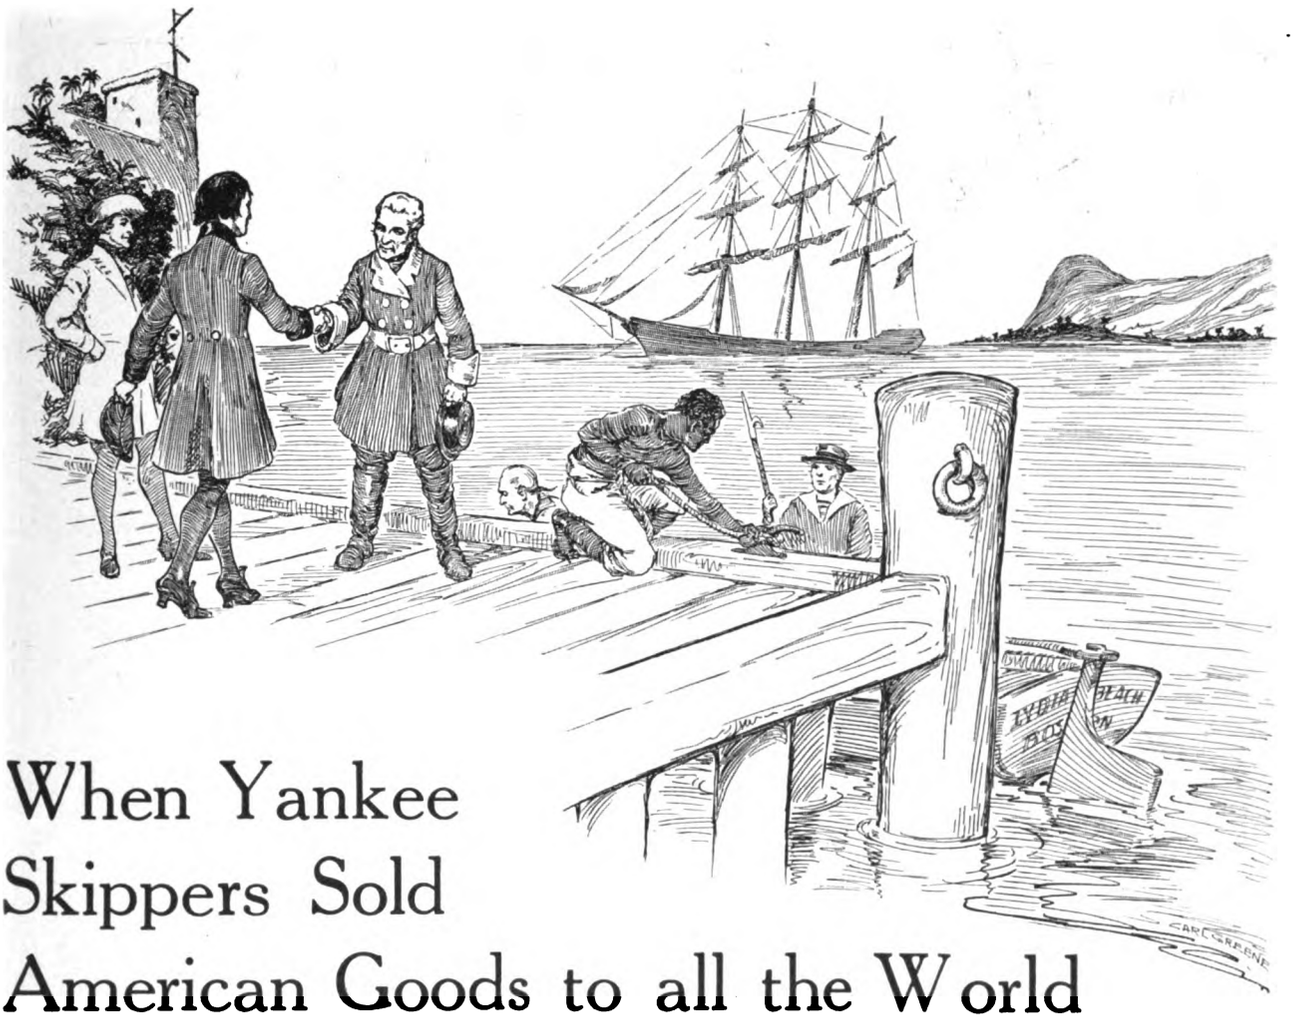
Flaxseed, meal, oat meal and bran which are used by many motorists, do not actually stop leaks they merely decrease them for a short time and these substances invariably stop up the regular water passages and are very difficult to clean out.

Johnson's Radiator Cement does not clog the tubes, it finds every leak no matter what part of the radiator or connections it is in, seals it up strong from the inside making it absolutely water tight. It does not injure the radiator, connections or rubber in any way.

If you allow the radiator to leak, trouble is sure to follow. Besides with a leaky radiator it is impossible to get proper circulation of water through the cooling system, thereby causing an overheated engine, scored cylinders and numerous other troubles.

Easy To Apply

Johnson's Radiator Cement comes in liquid form and is very easy to use. First drain the radiator, mix the cement with warm water and pour into radiator, run the engine for ten minutes then every leak in the radiator, water jacket and connections will be permanently stopped. The surplus cement left in the water, closes automatically new leaks that may develop from time to time.



S. C. JOHNSON & SON, Dept. A RACINE, WIS.

Pints..... $1.00
Half-pints... .65

Insist upon your dealer supplying you with Johnson's Radiator Cement. Do not accept any substitute. If he is unable to supply you send your order direct to us and we will prepay the express to any point in the U.S. east of the Rockies.

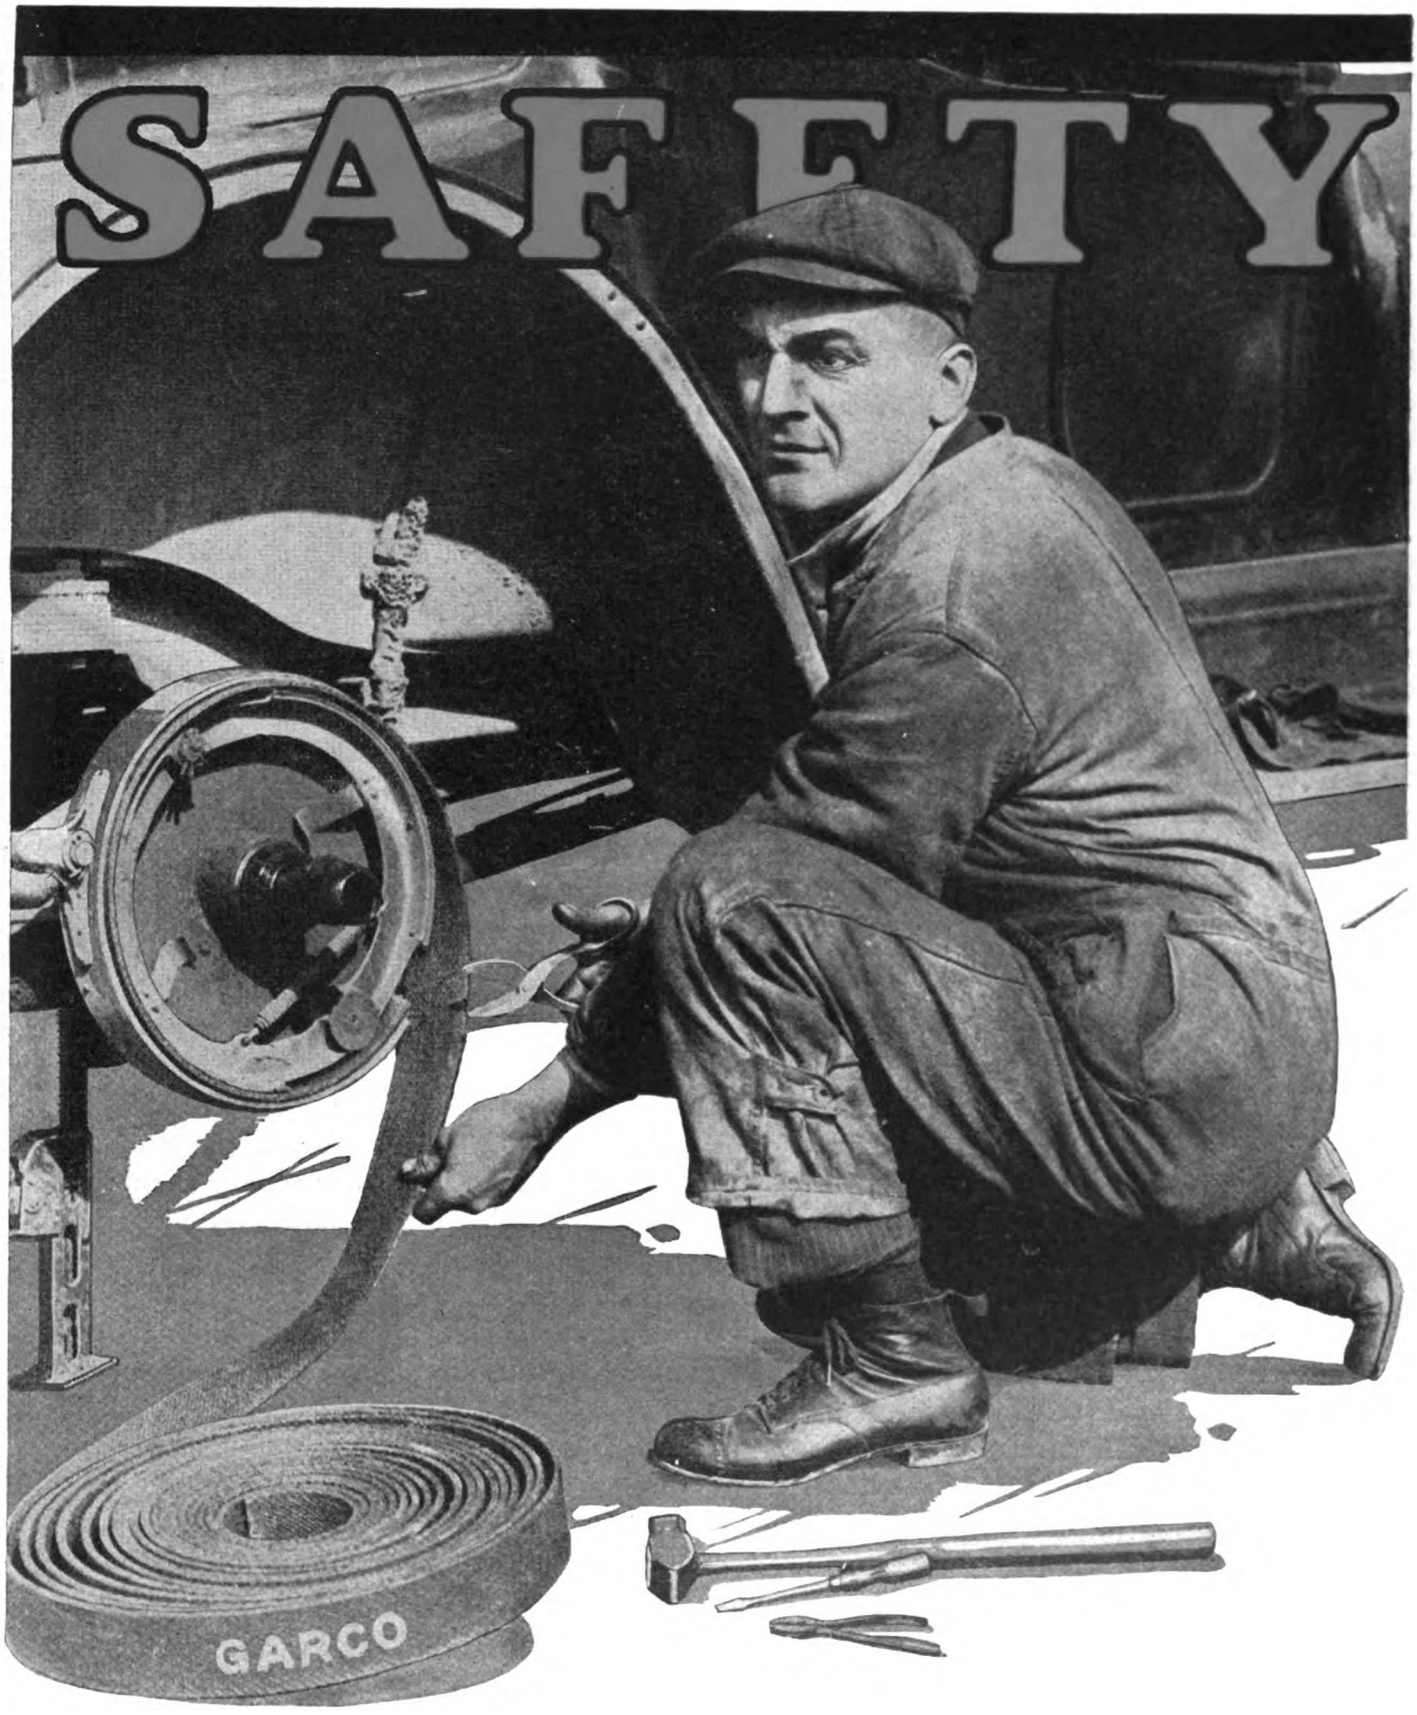
When Yankee Skippers Sold American Goods to all the World

They provided the most satisfactory export service imaginable. They trimmed off all the non-essentials in their dealings with the New England manufacturer and with their customers overseas. They paid cash for the goods they took abroad and, with their cargoes below decks, they sailed for the ports where the market was ripe.

It was their part to do the selling and adjustment of credits and exchange, leaving the American manufacturer undisturbed in the skillful production of his goods. Through the efforts of these early traders, many of our great manufacturing plants received the timely support that made them what they are today.

The Federal Export Corporation does business on this old Yankee plan. It is a ship-operating, selling and financing company, and through the magnitude of its organization it has facilities for selling motor cars, trucks or tractors that no house specializing solely in one class of goods can possess. Its commercial policy of strict compliance with local customs abroad makes it easier to introduce and maintain the sale of motor vehicles.



We invite your inquiry as to adapting the Fedex sales system to your own products.

INSURANCE

DONT think of the brake lining you sell as representing merely a certain sale—a certain profit. Look past this to the big, vitally important purpose that brake lining must serve and to the responsibility it must assume. And think in how great degree this responsibility comes back to you!

GARCO BRAKE LINING

is real *Safety Insurance*. It is an essential. And because it protects the life of the man who drives a car the question of price does not altogether determine his choice. Garco Dealers make fair profits because they do not have to cut the price.

Garco does not fail. Our pledge of highest quality is back of every foot of it. Solidly woven from high grade long-fibre asbestos; re-enforced by hundreds of brass wires woven into each foot, Garco holds with giant grip down to the last shred.

Back of Garco Brake Lining we have put an unusually complete line of sales helps supplied to all dealers free of charge. Write us today—let us tell you about them.

Garco Brake Lining is sold by all Jobbers. Ask yours to quote you on your requirements. We also manufacture a full line of asbestos automobile specialties, Transmission Lining for Fords, etc.

The Piston Ring That Guarantees Satisfaction

WHEN you equip a car with Burd High Compression Piston Rings, you know you have made a satisfied customer. No motor car owner can fail to note the improvement these rings have made in his motor car's performance. He finds his car has more power than it ever had before. It uses less gasoline and oil. It has more speed and compression. The cylinders are never choked with carbon.

BURD High Compression Piston Rings

Burd High Compression Piston Rings cannot leak. They enable the motor to deliver every possible bit of generated power.

The Burd Guarded Opening makes Burd Rings fit tight and ***stay*** tight. There is no gap through which the power can escape as in the ordinary rings.

At all times, the rings are in perfect contact with the cylinder walls. ***The guard seals the power in the cylinders.***

This Guarded Opening is a patented feature. No other ring has it. No other ring ***can*** have it.

And if you want your customers to get the extra power, economy, and complete satisfaction from their cars that this Guarded Opening makes possible, you must equip their cars with Burd High Compression Piston Rings.

BURD HIGH COMPRESSION RING COMPANY
Rockford, Ill.

The Advertising Service That Guarantees Sales

A NATION-WIDE advertising campaign, supplemented by a complete dealer service, tells motor car owners just where Burd Rings excel and why. This nation-wide campaign will educate motor car owners to the necessity of selecting their piston rings with the greatest care, and will also sell them Burd High Compression Piston Rings.

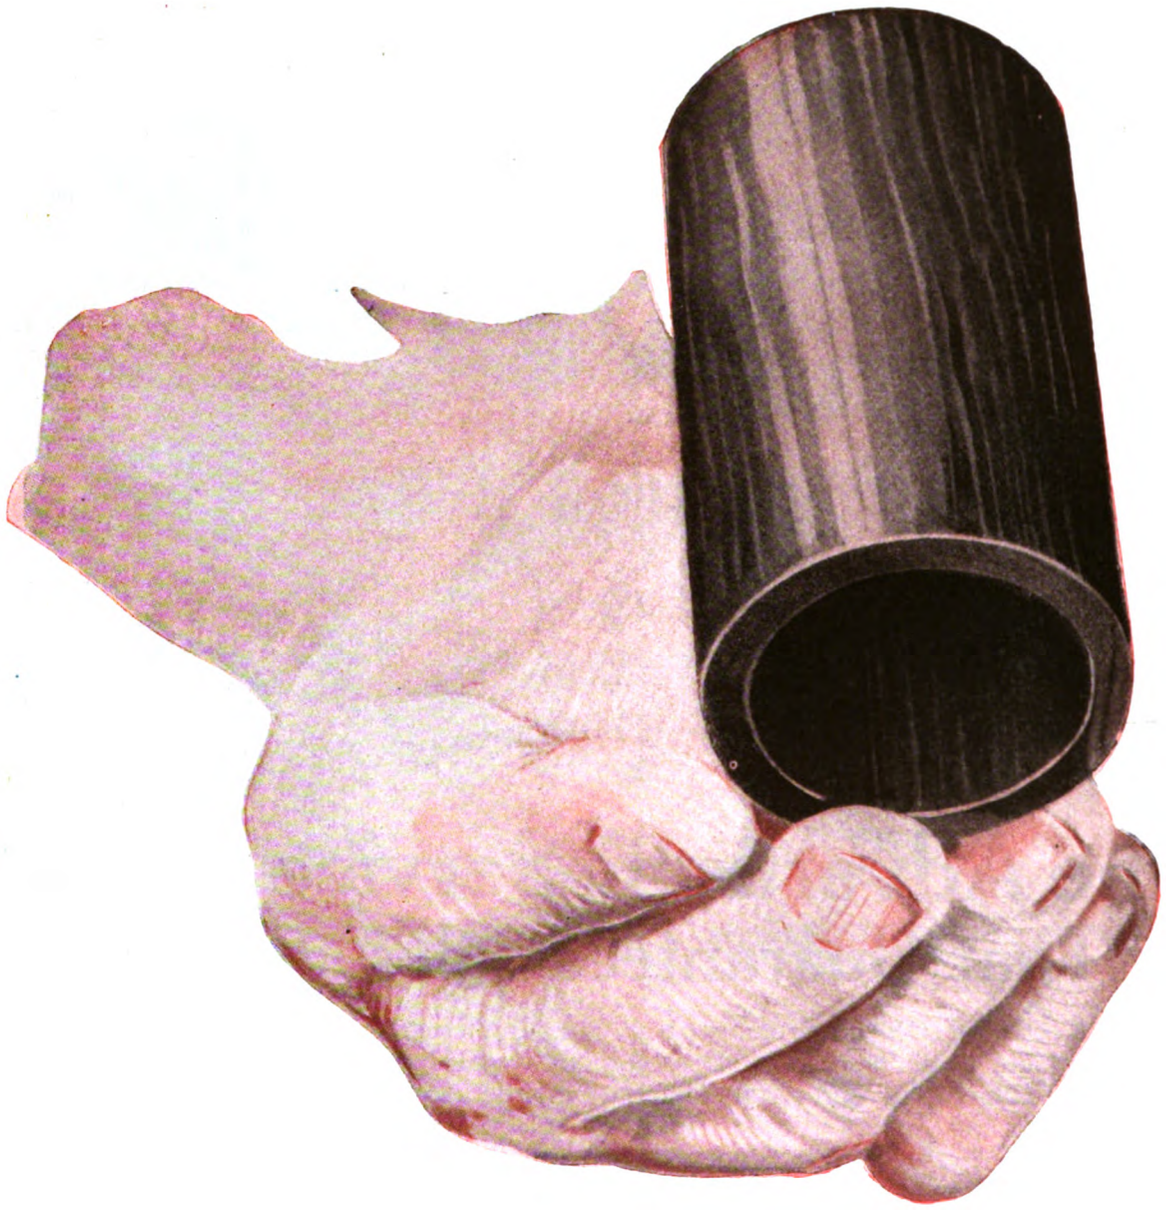
BURD High Compression Piston Rings

The first full-page advertisement appeared in The Saturday Evening Post on January 5th.

This will be followed with other full-page, equally forceful and selling advertisements.

But our dealer service does not stop there. It goes much farther.

A supplementary dealer advertising service, including booklets, letters, wall cards, show case displays, etc., is furnished you absolutely free.



Accessory dealers and garagemen are every day finding more motor car owners insisting on BURD Piston Rings.

Many more thousands are bound to be won over by our nation-wide campaign. Are you ready to meet this insistent demand? If not, write your jobber, or direct to us today for full information and prices.

TRADE MARK REG. U. S. PAT. OFF.

IMPREGNATED WOOD OIL-LESS BUSHINGS

YOU see illustrated on these pages two different kinds of *self-lubricating* bushings.

They are everywhere known by machinery-wise men as "Genuine Graphited *Oil-less* Bushings."

Millions are installed each year in hundreds of widely different types of machinery.

They are used and endorsed by the United States Government for use in Battleships, Destroyers, Submarines and Aeroplanes.

They are used and endorsed by the leading manufacturers of automobile trucks, passenger cars, airplanes, tractors, pumps, windmills, gas engines, farm, textile, shoe, mine, confectionery and many other types of machinery.

Truck and Car Manufacturers are using these Oil-less Bushings in certain places about their products. They find this a very practical method of prolonging the service life of those products, for the following reasons:

Grease and Oil Cups are placed on bushings for the obvious purpose of oiling them. A Bushing that fails to receive proper lubrication wears out quickly.

It is not a question of how good the bushing is or how carefully it is installed. If it is not kept properly lubricated, it will wear out *fast*, thereby causing the owner considerable annoyance, possible accident, and frequent overhauling expenses.

BOUND BROOK

TRADE MARK REG. U. S. PAT. OFF.

GRAPHITE AND BRONZE OIL-LESS BUSHINGS

There are many bushing places about motor cars and trucks which are continually liable to neglect because of their inaccessible location.

As a matter of fact, three out of four drivers do neglect to keep the vital, but inaccessible, bushings properly lubricated.

So, far sighted manufacturers use *oil-less* bushings at such inaccessible points—bushings that run smoothly and last a long time with or *without* continuous lubrication, and *in spite of* neglect.

Genuine Graphited Oil-less Bushings safeguard machinery. They contain within themselves sufficient lubricant to last their lifetime. Oiled or not oiled, attended to or neglected, they continue to run smoothly and efficiently, keeping machinery on the job, in good order, that otherwise might be held up or completely out of service.

All Genuine Graphited Oil-less Bushings have always been made at Bound Brook, U. S. A.

Make Your Ford "Ride Like a Young Packard"

"WE find them eminently satisfactory, making a Ford ride like a young Packard." Those are the words of one enthusiastic user of Aitchandee Shock Absorbers. Another says, "If every Ford owner would try your Absorbers for fifty miles over rough roads, I venture to say you would be unable to fill your orders."

"Save tires, and enough wear and tear on the car to pay for themselves in the first three or four months," says an Aitchandee owner in Brooklyn, New York. A Tennessee man says, "My Ford rides like a car with a long wheelbase, equipped with your Shock Absorbers."

Over 150,000 Ford owners are enjoying the advantages of the Aitchandee.

How about you?

Can you afford to suffer the discomfort, to wear out tires, to weaken your Ford, when Aitchandee Shock Absorbers would, at small cost, immediately change the entire situation?

AITCHANDEE

"TRADE-MARK REGISTERED"

Shock Absorbers

On the Ambulances in France

Back of the lines, where roads are broken up by shell holes, Aitchandee Shock Absorbers on the ambulances are protecting wounded soldiers against the jolts and jars. Aitchandee Shock Absorbers never would have been used unless their merit had been proved beyond question.

Why don't *you* take advantage of Aitchandee comfort?

The cantilever principle, first developed in Aitchandees, gives a different tension on the upward and downward thrust.

This Aitchandee cantilever eliminates a sharp rebound. The Aitchandee cantilever carries the body forward on practically a straight line while the wheels follow the contour of the road.

That is why the Aitchandee Shock Absorbers make a Ford ride like a long wheelbase — Pierce-Arrow, Locomobile and Packard.

Make *your* Ford ride like a car with a wheelbase of 140 or 150 inches.

Ask for the facts today. Read below.

"Iron" the Roads for Fords

When you put Aitchandees on your car, you've made it over as far as comfort is concerned. Just a few hundred yards driving anywhere will convince you. Whether you test Aitchandees on rough roads or city pavement, *you'll notice the difference.*

Why don't you put Aitchandee Shock Absorbers on your car? The expense is practically nothing when you consider the results in comfort, tire saving, and protection to the mechanism of the car.

Remember that Aitchandee Shock Absorbers have tremendous endurance. The springs are made of the best spring wire steel. Specially annealed malleable iron affords practically unbreakable arms. Lock bolt construction makes oiling unnecessary. Aitchandees are easily applied. No holes to bore. Appearance of car is not marred. Aitchandees once on are scarcely visible.

Hundreds of Miles More From Every Tire

Vibration and shocks are so perfectly absorbed by Aitchandees that the tires have less strain and consequently last longer. Aitchandees will quickly save their cost in tire protection alone.

And tires are a bigger item than ever before in the operation cost of your Ford.

Make Your Ford Last Longer

through the cushioning effect of Aitchandees.

Road gulleys and ruts destroy the finest steel. Motor, bearings, transmission, all suffer.

But Aitchandees reduce these hammer blows so that the Ford stands up better. Fewer breakdowns, lowered repair cost, longer life. 150,000 other Ford owners know this to be true. You must equip with Aitchandee Shock Absorbers if you really want to get the longest service from your Ford.

WRITE—We'll Put Big Car Comfort Into Your Ford—Get Facts—No Obligation

Find out at once what Aitchandee Shock Absorbers will do for you. A postal will bring you the facts. We'll prove to you Aitchandee results *conclusively.* If we don't you're under no obligation in any way.

We'll tell you where you can inspect Aitchandee Shock Absorbers and see for yourself how they operate and why they give greater comfort, economy and long life to your Ford. Write us at once.

STUDEBAKER

Presents

THREE NEW CARS

The Four - The Light Six - The Big Six

Beautiful in design
Thoroughly modern
Mechanically right

The BIG SIX

Digitized by Google

THE NEW SERIES 19 STUDEBAKER CARS, in three models, embody our long experience together with the latest and greatest achievements of some of the ablest and most experienced engineers and production experts in the automobile industry. These cars are *new throughout*, with improved motors, intermediate transmission, new axles, bodies, tops, windshields, radiators, hoods, fenders, etc. They are beautiful in design, thoroughly modern and mechanically right.

Before finally approving these cars for production, experimental models of each car were driven 30,000 miles under the severest conditions, through the mountains and country roads of the United States and Canada, and finally over the Chicago Speedway. Never were we better satisfied with the performance of any cars, in power, speed, endurance and riding comfort. To make assurance doubly sure, the experimental cars, now running on the Chicago Speedway, will be kept running continuously until they negotiate 50,000 miles or more, about twice the distance around the earth. These cars are the masterpieces of the Studebaker organization.

The new cars include three models, all entirely different and each with an individual appeal. *We know* these cars will give our customers maximum service and economy, with practically no expense for repairs except from wear and tear or in the case of accidents.

The LIGHT-FOUR Five-Passenger, shipping weight 2,400 lbs., wheelbase 112 inches, tires 32"x3½", 35 H.P. motor, 3½"x5", hot spot manifold, intermediate transmission, improved semi-floating rear axle, Studebaker blue body finish, applied in twenty-four operations, French plaited upholstery. Price for touring car or roadster, $895 f.o.b. Detroit.

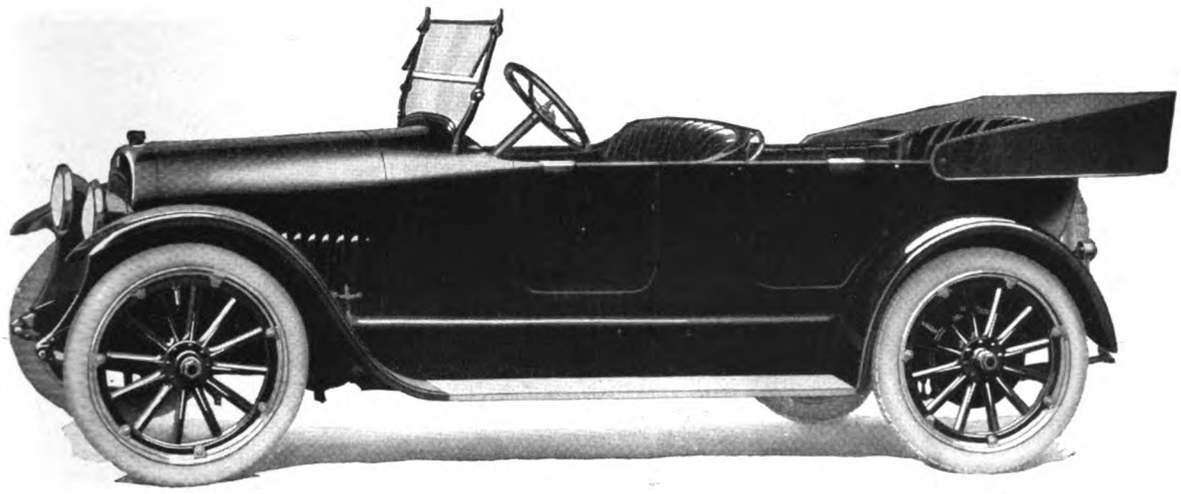
The LIGHT-SIX Five-Passenger, shipping weight 2,800 lbs., wheelbase 119 inches, tires 32"x4", 50 H.P. motor, 3½"x5", hot spot manifold, intermediate transmission, improved semi-floating rear axle, either blue or maroon body finish, applied in twenty-four operations, French plaited upholstery. Price for touring car or roadster, $1295 f.o.b. Detroit.

The BIG-SIX Seven-Passenger, shipping weight 3,000 lbs., wheelbase 126 inches, tires 33"x4½", 60 H.P. demountable head motor, 3⅞"x5", hot spot manifold, intermediate transmission, improved semi-floating rear axle, either chrome green or maroon body finish, applied in twenty-four operations, French plaited upholstery. Price for touring car, $1695 f.o.b. Detroit.

During 1915, 1916 and again in 1917, more Studebaker cars were registered and operated in the city of Detroit—the city which knows automobiles and the standing of manufacturers—than any other make of car selling over $500. The lesson is obvious.

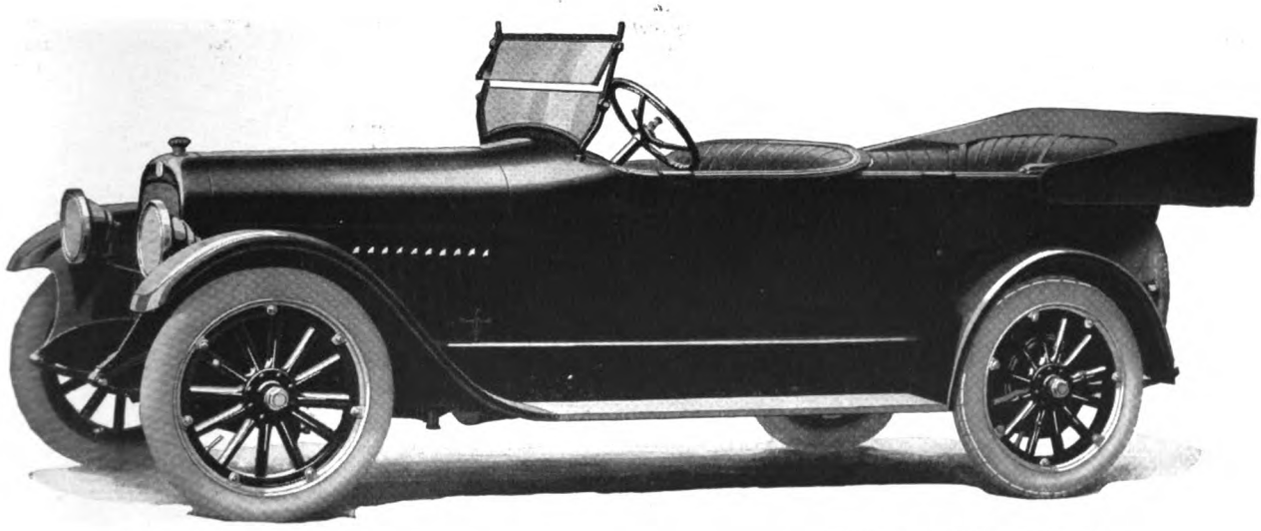
Studebaker factories at Detroit, South Bend, Chicago and Walkerville, occupy 168 acres, contain 4,704,118 square feet of floor space, and represent an investment of over $15,000,000. There are no "assembler's" profits in the prices of Studebaker automobiles, because we design and manufacture our parts in our own plants, saving our customers from twenty to thirty per cent.

We commend these cars to the public and seek their patronage, in confidence that they will be entirely pleased with their purchase.



THE STUDEBAKER CORPORATION OF AMERICA,

A R Erskine



President.

South Bend, Indiana,
January 3d, 1918.

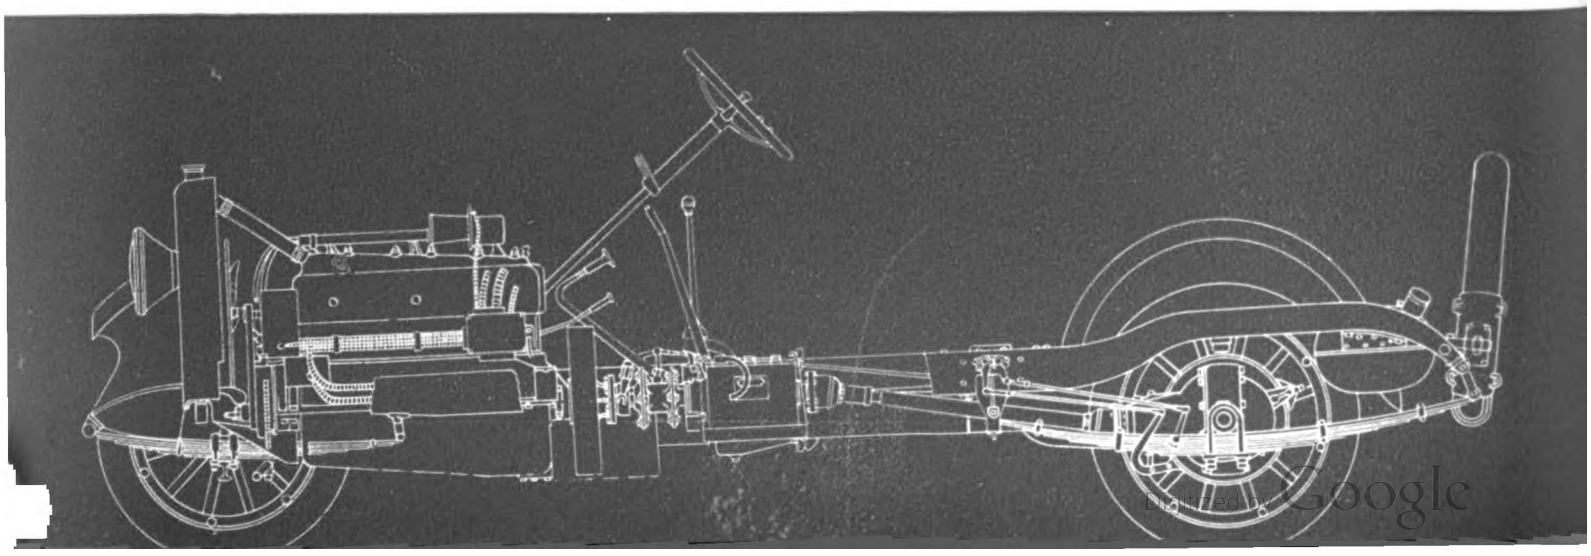
SPECIFICATIONS—Series 19—Studebaker Cars

The FOUR



Seating Capacity, five passengers. *Wheelbase*, 112 inches. *Motor*, four cylinders, cast en bloc, L-head type, 3½" x 5"; 35 h. p. *Lubrication*, splash and positive distribution. *Cooling System*, centrifugal force pump circulating system; tubular radiator; 18", six-blade fan. *Carburetion*, Schebler carbureter, with new type hot spot intake manifold. *Gasoline System*, 14-gallon tank in rear; vacuum feed. *Electric System*, two-unit Studebaker-Wagner. *Ignition*, generator-storage-battery ignition, with Remy coil and distributor. *Electric Lights*, large headlights with improved deflecting and diffusing lenses, speedometer light, tail light. *Clutch*, aluminum leather-faced cone clutch with dampening brake. *Transmission*, intermediate—three speeds forward, one reverse. *Gear Ratio*, 4 to 1. *Rear Axle*, Studebaker, improved semi-floating, spiral bevel gear drive, full Timken bearing equipment. *Drive*, Hotchkiss. *Springs*, front and rear semi-elliptic; front 34½ x 1¾, 7 leaves; rear, 50¼ x 2, 7 leaves, underslung. *Tires*, 32 x 3½; safety tread on rear. *Fenders*, heavy pressed steel, crowned. *Upholstery*, French plaited. *Top*, leatherized, one-man type; Blackmore storm door curtains. *Equipment*, rain vision slanting windshield; 3½" carpet-covered footrest in tonneau; complete set of tools; electric horn; electrically-lighted instrument board on which are mounted Stewart-Warner Speedometer—driven from propeller shaft—oil indicator, ignition and lighting switch, carbureter adjusting devices; combination nickel robe and hand rail extending full width of front seat; gasoline gauge on tank in rear. *Color*, Studebaker blue. *Price* for touring car or roadster, $895 f.o.b. Detroit.

The LIGHT-SIX

Seating Capacity, five passengers. *Wheelbase*, 119 inches. *Motor*, six cylinders, cast en bloc, L-head type; 3½" x 5"; 50 h. p. *Lubrication*, splash and positive distribution. *Cooling System*, centrifugal force pump circulating system; tubular radiator; 18", six-blade fan. *Gasoline System*, 17-gallon tank in rear. Vacuum feed system. *Carburetion*, Schebler carbureter, with new type hot spot intake manifold. *Electric System*, two-unit Studebaker-Wagner. *Ignition*, generator-storage-battery ignition, with Remy coil and distributor. *Electric Lights*, large headlights with improved deflecting and diffusing lenses, speedometer light, tail light. *Clutch*, aluminum leather-faced cone clutch with dampening brake attachment. *Transmission*, intermediate—three speeds forward, one reverse. *Gear Ratio*, 4 to 1. *Rear Axle*, Studebaker improved semi-floating, spiral bevel gear drive, full Timken bearing equipment. *Drive*, Hotchkiss. *Springs*, front and rear semi-elliptic; front, 38 x 2, 7 leaves; rear, 56 x 2, 8 leaves, underslung. *Tires*, 32x4; safety tread on rear. *Fenders*, heavy pressed steel, oval crown design. *Upholstery*, French plaited. *Top*, leatherized one-man Gypsy type, bevel French plate glass windows in rear; Blackmore storm door curtains. *Equipment*, rain vision slanting windshield; 3½" carpet-covered footrest in tonneau; complete set of tools; electric horn; electrically-lighted mahogany instrument board on which are mounted Stewart-Warner Speedometer—driven from propeller shaft—oil indicator, ignition and lighting switch, carbureter adjusting devices; combination nickel robe and hand rail extending full width of front seat; mahogany glove box, with lock, in back of front seat; gasoline gauge on tank in rear. *Colors*, choice of blue or maroon. *Price* for touring car or roadster, $1295 f.o.b. Detroit.

The BIG-SIX

Seating Capacity, seven passengers. *Wheelbase*, 126 inches. *Motor*, six cylinders, cast en bloc, L-head type, demountable head; 3⅞" x 5"; 60 h. p. *Lubrication*, splash and positive distribution. *Cooling System*, centrifugal force pump circulating system; tubular radiator; 18" six-blade fan. *Gasoline System*, 17-gallon tank in rear. Vacuum feed. *Carburetion*, Ball & Ball carbureter, with new type hot spot intake manifold. *Electric System*, two-unit Studebaker-Wagner. *Ignition*, generator-storage-battery ignition, with Remy coil and distributor. *Electric Lights*, large headlights with improved deflecting and diffusing lenses, speedometer light, tonneau light with convenient extension; tail light. *Clutch*, aluminum leather-faced cone clutch with dampening brake attachment. *Transmission*, intermediate—three speeds forward, one reverse. *Gear Ratio*, 3.7 to 1. *Rear Axle*, Studebaker improved semi-floating, spiral bevel gear drive, full Timken bearing equipment. *Drive*, Hotchkiss. *Springs*, front and rear semi-elliptic; front 38" x 2", 8 leaves; rear, 56" x 2", 9 leaves, underslung. *Tires*, 33" x 4½"; safety tread on rear. *Fenders*, heavy pressed steel, distinctive crown design. *Upholstery*, French plaited. *Top*, leatherized one-man Gypsy type, bevel French plate glass windows in rear; Blackmore storm door curtains. *Equipment*, rain vision slanting windshield; 3½" carpet-covered footrest in tonneau; complete set of tools; electric horn; electrically-lighted mahogany instrument board on which are mounted Warner Speedometer—driven from propeller shaft—oil indicator, ignition and lighting switch, carbureter adjusting devices, ammeter and Waltham clock, combination nickel robe and hand rail extending full width of front seat; mahogany glove box with lock, on back of front seat; gasoline gauge on tank in rear. *Colors*, choice of chrome green or maroon. *Price* for touring car, $1695 f.o.b. Detroit.

The Everlasting Battery

Never before in the history of the automobile industry has there been offered a battery with such an inherent capacity for long, satisfactory service.

PERMALIFE BATTERIES, in every process of manufacture, from the forming of the specially designed lead grids to the last thorough test in the Permalife Laboratory, bespeak permanency.

THE LIFE OF A BATTERY is in the plates and here lies the fundamental reason for Permalife superiority.

PERMALIFE PLATES are *packed—not pasted*—with an active material of such density as to make them well-nigh indestructible. And yet, this active material presents a surface to the electrolyte which insures quick and free chemical action—and a resultant rapid current output.

The **harmful sulphation,** which is the prevailing disease among other makes, **is completely prevented in Permalife Batteries.** Barring abusive treatment Permalife Batteries are positively non-sulphating.

DEALERS—The Permalife merchandising plan presents a unique opportunity to capture and keep the bulk of your local battery business. It is of vital importance to you because it insures a permanent battery service to your patrons and gives you their permanent patronage.

Let us show you the profit getting possibilities of Permalife.

COE-STAPLEY

Our Announcement

COE-STAPLEY is a name well and favorably known to car manufacturers and the large jobbers because of its many years of straight dealing.

Previously, all our attention has been devoted to supplying good hand pumps to large-volume buyers—principally car makers.

With this announcement we enter the jobbers' field, intending to do business with all recognized jobbers on a basis justified by their requirements.

We shall sell only to jobbers—because we feel that through jobbing channels we find the most economical means of distribution. Thus our merchandise will cost both dealer and consumer less.

We shall co-operate with all of our jobbers by advertising to the dealers, who are the jobbers' *consumers*—and to car owners throughout the country.

We shall co-operate even more intelligently, however, with all four factors in the distribution of automobile accessories—manufacturer, jobber, dealer and consumer—by selecting the articles we shall manufacture and sell on the basis of demand, suitability, novelty, appearance and economy.

For the rest, the Coe-Stapley Mfg. Corporation is an organization whose financial resources are, for all practical purposes, unlimited, and whose manufacturing requirements will be amply taken care of by our splendidly equipped plants at Bridgeport, Conn., and Brooklyn, N. Y.

We shall soon present to the trade a diversified line—our pumps, a jack and several other items we have in view. The first item for which we ask your consideration is presented on the opposite page. We selected the Peteler Auto Jack from the field as the one lifting jack whose design, quality and future warranted us in putting behind it the reputation, the resources and the selling effort of the Coe-Stapley organization.

E. B. Shoemaker

Secretary-Treasurer.

Coe-Stapley Mfg. Corporation

Executive Offices: 115 Broadway, New York

Factories: Bridgeport, Conn., and Brooklyn, N. Y.

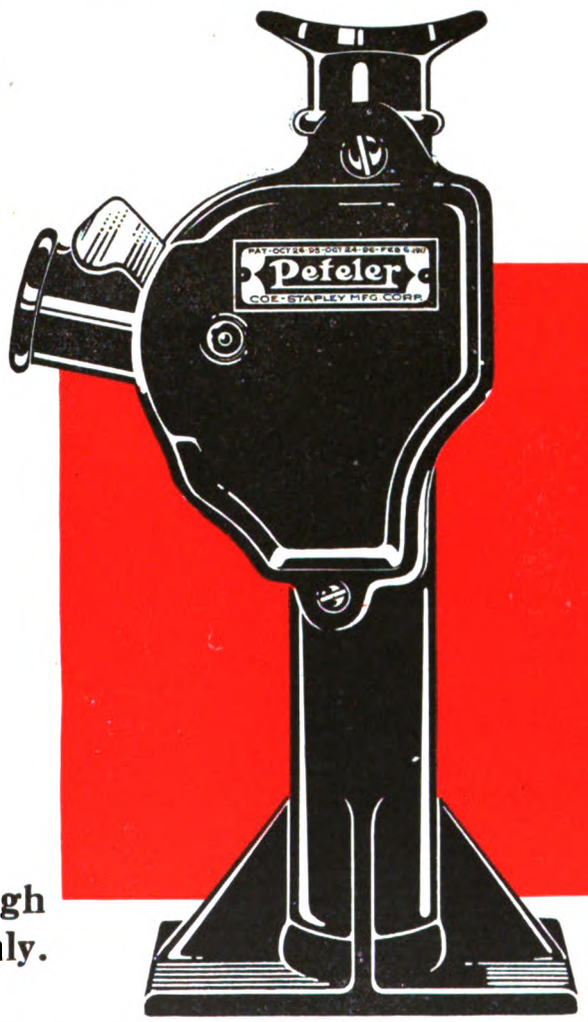
Manufacturing Corporation

$6 for the best Jack in the world

Peteler AUTO JACK

$6 for the best Jack in the world

The new Peteler Jack is the best Jack in the world—even better than the previous model Peteler Jack.



It's simple—a few moving parts and nothing to get out of order.

It's sturdy—the working parts are of the finest tool and cold rolled steel, the case of malleable iron.

It's powerful — capable of raising 3000 lbs.—a half ton of overstrength.

It's efficient—does everything a Jack could be asked to do and without effort.

It's fast—and no waste of time.

The Peteler Jack is greatest in action.

It has a long telescoping handle—can be slid under the car without kneeling.

It has a short stroke—can be slid way under and yet operated.

It raises the load easily—quickly.

It lowers with the same facility—a simple turn of the handle operates a pinion and reverses from the upward to the downward action.

Relieved of the load—a lift of the handle allows the rack to drop down and the Jack can be withdrawn.

The best Jack in the world.

Sold through jobbers only.

Orders filled in rotation.

Read What Car Owners Say:

Rev. H. Voisin, Red Deer, Albta, Canada.
So far your carburetor has given me good satisfaction; several times I have averaged 30 miles to the gallon. Sept. 17, 1917.

Methodist Episcopal Church, Gustave A. Frodle, Pastor, Blunt, South Dakota.
Some time ago I ordered a Ford size carburetor from you. After a good test I find it to be THE Carburetor. Sept. 8, 1917.

W. T. Thompson, Maricopa, Cal.
I have purchased one of your carburetors and I like it fine and would like to take the agency for them for the State of California or if not for the whole state would like for Kern County. Please send me your lowest price and all your particulars as soon as possible as I have three sales in view. August 30, 1917.

P. H. Grace, Los Angeles, Cal.
The carburetor received and I make 35 miles to the gallon of distillate. Sept. 12, 1917.

Chas. H. Wishmeier, Indianapolis, Ind.
Carburetor received and after attaching on Saturday last I drove the car 128½ miles, part of this trip through Brown County, the hilliest part of Indiana. Almost all the hills were very rough, making it impossible to attempt them on high, one especially being three miles over, took us a half hour to cross, all of which was run on low. I was following a friend of mine who also had a Ford standard carburetor and found that when we came to a hill where the roads were good I would have to lie back about a quarter of a mile behind him, as even with this distance between us I would almost always catch him before he got to the top, then have to follow him up the rest of the way on low. My wife used to be afraid of every little hill but after putting on the SUNDERMAN she said she is willing to go any place now. When we got home after this 128½ mile run I found that I had used just 5 gallons of gas, almost 26 miles per gallon. I certainly was well pleased as I made no effort to run the car to save gas. The best I have ever done before was 22 miles per gallon all on a level road. August 6, 1917.

Edw. G. McCarthey, Denver, Colo.
I received and installed your carburetor yesterday; after two hours test I found it to be just as you claimed. I would like your agency proposition as I have a large order for you.
Sept. 18, 1917.

John L. Bradley, 243 W. 50th St., N. Y. C.
Since having your carburetor attached to my car I have increased mileage very near double, that is from about 14 I was getting to close to 28 miles with it on. I have out of necessity had to put this car through the severest tests demonstrating our shock absorbers, and you can see from this that the saving in gasoline alone is really remarkable, and with this the increased power I have received makes it an *ideal* carburetor. Sept. 28, 1917.

Standard Poster Advertising Co., E. T. Broderick, Gen. Mgr., New Rochelle, N. Y.
I want to say right here if it wasn't the best I could find, price and all considered, that I would not have anything to do with it, and here in New Rochelle I have an Oakland 40 and three Fords using the carburetor and in Peekskill two Fords, and am anxious to get it on the Cadillac.
Oct. 10, 1917.

W. H. Fisher, Grand Rapids, Mich.
The writer has now used one of your carburetors a little over one year and am more than pleased with the results as I am getting very good mileage, and it gives me more power and speed. Made a trip down in Ohio a couple of weeks ago and averaged a little better than 27 miles to the gallon. Oct. 17, 1917.

R. F. Sturgeon, Empress, Alberta, Canada.
The carburetor you sent me is doing great work. Have got as high as 30 miles on a gallon with my 1913-Buick. I used to think I was doing fine if I got 15 miles out of the old one. I just put in new cylinders in the car as the old ones were scored, so there is no telling what I will get now, as I made the 30 with the scored cylinders. I made one trip 155 miles actual mileage (not speedometer) on 5 gallons (Imperial) of gasoline with three badly scored cylinders and a lot of oil working through above the pistons. Am perfectly satisfied with the carburetor. Sept. 20, 1917.

Elmer McKee, Richmond, Indiana.
I am using one of your carburetors with very good satisfaction on a Lexington car.
Oct. 25, 1917.

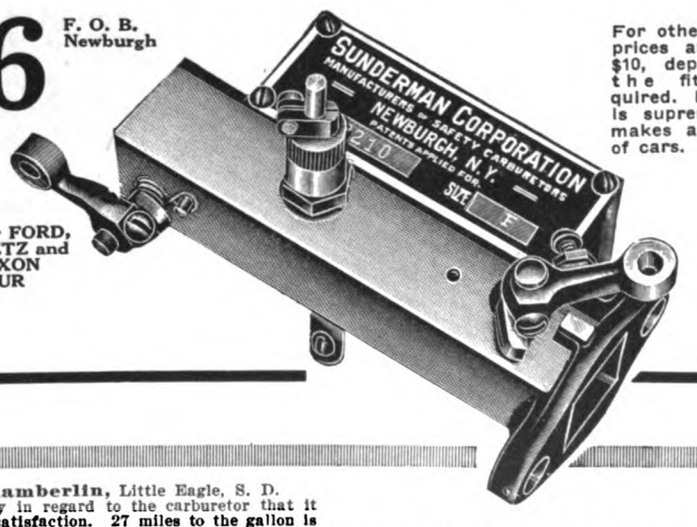
D. Q. Johnson, Santa Rosa, Cal.
I received the carburetor and it works at all times to perfection, making the old Buick "40" run like a modern car. Oct. 7, 1917.

Our Satisfied, Enthusiastic Money-Making Dealers

Our advertising is an easy job. In every mail, every day, surprised and satisfied users, contented dealers who are making profits on Sunderman Carburetors, write us enthusiastic letters of endorsement. Printed just as they come to us, they make excellent advertising copy.

They Prove the Value of the Sunderman
They Prove the Market and the Profits

The Sunderman Carburetor is without a peer in the field of automobile accessories and parts—it is the only instrument that will make substantial profits for dealers, and at the same time make more money for the car owner who buys it.



The Saving in Gasoline Pays the Owner a Perpetual Profit

The Sunderman Carburetor is uniformly saving from 30 to 50% in gasoline on every car. Look at the letters on the left of this page, and let the owners prove this statement.

This saving alone sells the carburetor—the extra power, flexibility, pick-up and hill climbing ability come as good measure—an unexpected dividend on the investment.

SUNDERMAN
Vacuum Carburetor

$6 F. O. B. Newburgh

For other cars the prices are $8 and $10, depending on the fittings required. Its service is supreme on all makes and models of cars.

For FORD, METZ and SAXON FOUR

O. W. Chamberlin, Little Eagle, S. D.
I will say in regard to the carburetor that it gives good satisfaction. 27 miles to the gallon is about the best we have done, but the roads are very bad and twenty miles is very good, in fact, about 15 is the average for a Ford. My Ford is mechanically in bad shape, which I expect to remedy and then will give these people something to think about. Oct. 7, 1917.

Chas. C. Kneeland, Groveland, Mass.
In regard to the carburetor I received from you a short time ago will say that I installed same on my Maxwell Roadster and find it is the best thing in the line of a carburetor that I have ever seen, in fact I am doing stunts with my car that seem impossible to the average car owner. I gave a demonstration to a friend of mine and on the strength of it I am ordering one for him. May 20, 1917.

F. H. Pierson, Poughkeepsie, N. Y.
I am sending you carburetor which I used on my Maxwell car with such good results that when I disposed of it I removed the carburetor, which I wish you would change and adjust so I could use it on my Ford. May 17, 1917.

H. W. Stebbins, Watertown, N. Y.
I am using one of your carburetors on a 22 H.P. Motor with so much satisfaction that I beg to inquire if you recommend that the same will work equally as well on a 8-10 H.P. 4 cyl. 2 cycle Motor. June 15, 1917.

Bourne Brothers, House Painters and Interior Decorators, Milton, Mass.
I have had one of your carburetors put on my Ford truck and am much pleased with it.
July 16, 1917.

D. G. Douglass, Washington Mills, N. Y.
I bought a carburetor from you last year and it certainly did fine work. My Overland never ran better since I had it than since I have installed this carburetor. July 2, 1917.

F. E. Howard, Faribault, Minnesota.
Have a Sunderman Carburetor on a Reo car and it works OK. Will run on kerosene when the motor is hot. July 12, 1917.

John W. Shaffer, Kelly-Springfield Tires and Tubes, Delphi, Ind.
I recently purchased through the Universal Accessories Co. a Sunderman Carburetor and installed it in a 1918 Ford car. The results so far have been so surprising that I am writing in regard to territory. June 20, 1917.

A. M. Lockett & Co., New Orleans, La.
So far as economy is concerned, we do not think that your carburetor can be excelled, as the mileage obtained with the old carburetor was from ten to eleven miles per gallon of gasoline, whereas we are now getting from eighteen to nineteen miles per gallon. May 25, 1917.

The New Adirondack Garage, T. J. Lynch, Prop.
Kindly ship me two more carburetors for small Saxon four-cylinder runabout cars. I have used four or five of them and can place at least 100 more. They are giving entire satisfaction and great mileage. May 24, 1917.

J. Bergquist, Fitchburg, Mass.
Have received and tested out Ford Carburetor you sent me recently. Find that it is working very good and I could without doubt sell a large quantity of them in this district. June 4, 1917.

Simmons Hardware Co., St. Louis, Mo.
Recently we wired you an order for a SUNDERMAN CARBURETOR to be used on a Ford car. This carburetor was for one of the employees of this firm and he states that it is giving excellent service. June 12, 1917.

H. H. Palmer Garage, Bishop Hill, Ill.
I sent to Chicago and got two of your carburetors and put them on Ford cars and they worked fine. June 22, 1917.

P. H. Brown, Auto Repairing, Chepachet, N. Y.
I installed one of your carburetors on a Ford car and it worked so fine would like to sell them. July 27, 1917.

Dealers Who Handle Sunderman Carburetors Write as Follows:

Redden Motor Truck Co., Inc., 235 West 58th Street, New York.
Recently it was brought to my attention that the Sunderman Carburetor was a decided gasoline saver on a Ford car, and as my firm are always on the lookout for anything that will reduce the operating expense of a Ford car, I took it as a personal matter to try out one of your carburetors. The performance of the carburetor is certainly satisfactory in every respect. I notice that it is hardly ever necessary to use a throttle when on country trips, as the carburetor seems to be in itself an automatic throttle when coming on to grades or when pulling is hard in heavy going. As for gasoline economy, on my last trip I used a trifle over 6½ gallons of gasoline on the run from Albany to New York. I certainly appreciate your arranging to have a service man at your factory on a holiday to attach a carburetor to my car.
Yours very truly,
L. S. HIGHAM, Sales Manager.
November 23, 1917.

Motor Car Equipment Co., Indianapolis, Indiana.
Received the carburetor and after installing it and getting the proper adjustment it certainly does work fine. Would like to try out one or two more before ordering in quantities. July 2, 1917.

The City Garage, Terlton, Okla.
Your carburetor arrived and we placed it on the Ford car and every one that has tried it thinks it works fine. July 11 1917.

Russell & Wineland Auto Repair Co., Berwyn, Neb.
We received the SUNDERMAN VACUUM CARBURETOR a few days ago and have tried it out on my Maxwell and find it very satisfactory. We want to handle them here. May 14, 1917.

Thomas McClusky, Los Angeles, Cal.
I will write you again in regard to the SUNDERMAN CARBURETOR, as I have so many calls for them and I could install lots of them, as every one that rides with me in my car wants me to get them one, and I tell them I will have some of them on hand shortly. If you can't do any better, send me literature and the prices so that I can satisfy those that I have promised. If you want me to have the agency let me know, and if so send me a half dozen at once, and by that time I can have you to send me fifty or more. And let me know the best price on them by large amounts. It would be impossible for you to get this little carburetor away from me if I could not get another one. Oct. 6, 1917.

Crown City Sheet Metal Works, Pasadena, Cal.
I am using one of your carburetors on a Ford machine which is giving almost double the mileage the one I took off did. I have never seen any carburetor to equal it. The machine runs smoother, with more power, and starts almost always on the first turn. Oct. 12, 1917.

Neikirk & Miller, Hardware Specials—Buggies, Implements and Autos, Greenspring, O.
We received carburetor for Ford car and have been using it since and have found it to be very satisfactory. June 14, 1917.

United States Automobile Supply Co., Omaha, Neb.
We have had very satisfactory results with the SUNDERMAN CARBURETOR and hope to greatly increase our sales in the near future. Oct. 24, 1917.

T. J. E. Pinson, Platte Center, Neb.
Once more I am impelled to write you about your carburetors. I now have 43 here working in good shape, they fire the engine all right, pull all right and have plenty of power. July 29, 1917.

Groveland Street Garage, Haverhill, Mass.
I ordered 6 carburetors yesterday, the 30th, and I wish to change that order and make it 12 in all, 10 Fords and 2 Maxwells. I wish to say that the carburetors are performing some wonderful stunts on the cars I have put them on. July 31, 1917.

G. D. Gates, Albion, R. D. No. 4 Pa.
Received the carburetor, and the Sunderman is the best I have ever used. I have sold a number of your carburetors and they all give good satisfaction. June 9, 1917.

N. J. Floan, Hibbing, Minn.
Received the carburetor, and the Sunderman installed and it works fine. I can sell quite a few here and would like to get agency for same. May 23, 1917.

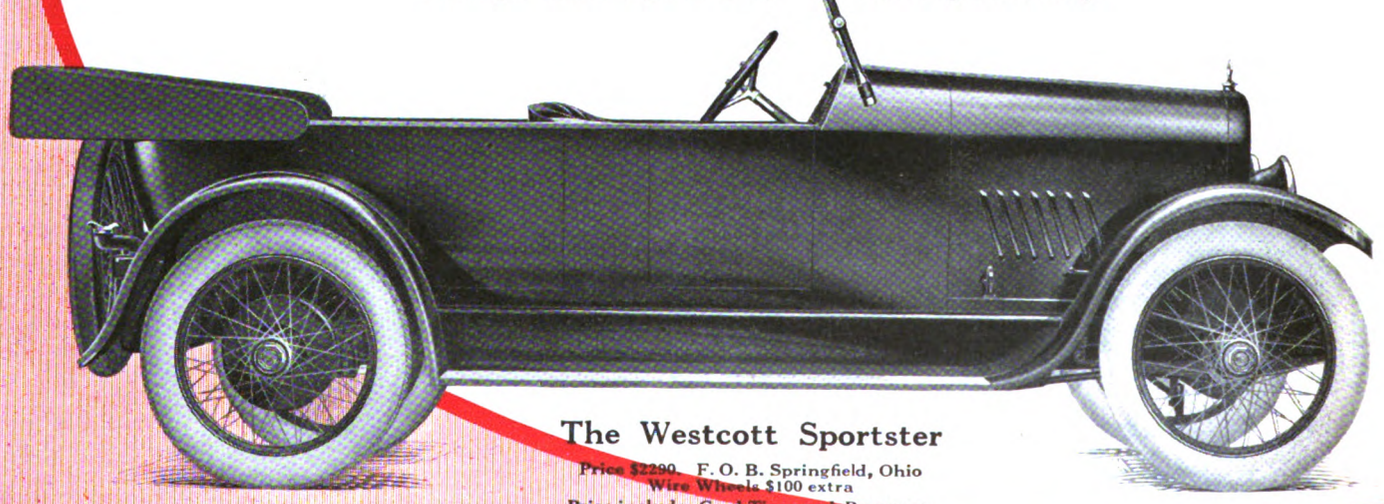
Westcott

THE Westcott Motor Car Company was the first to solve the problem of chassis lubrication by eliminating grease cups and installing wick-fed oil cups exclusively, and the first to equip all their open models with "*self-acting*" tops.

They foresaw the need of automatic regulation of motor temperature and incorporated thermostatic control in every Westcott power plant.



In like manner they have anticipated every requirement in body types so as to make the masterful all-season Westcott chassis available in just the style of car completely satisfactory to each buyer.

Now, though still midwinter, and while Westcott Convertible Sedans and Coupes are selling as fast as the factory can build them, the Westcott designers are ready with the most rakish summer model, the Westcott *Sportster*, whose every line and angle proclaim it the pace-maker in the ultra smart class.

Whether you are interested in motor cars from the standpoint of owner or distributor, your inspection of our offerings at the shows will convince you that the Westcott is the outstanding value of the year.

New York Show Space B-1.

Chicago Show Space B-2, 1st Regt. Armory.

Sell the Public What It Wants

YOUR customers are not demanding that a car have a certain number of cylinders.

They are not even demanding that a car get its power from an internal explosive engine.

They are not demanding gas cars any more than they are demanding steam cars.

They are not demanding anything in an automobile except a better performance.

What your customers want is a car which will run with a soft, smooth, gliding motion—without any noise or vibration, even at highest speeds—a car whose energy does not depend upon the speed of a fly-wheel; but whose power is stored in advance—whose maximum effort is just as available at low speeds as at high.

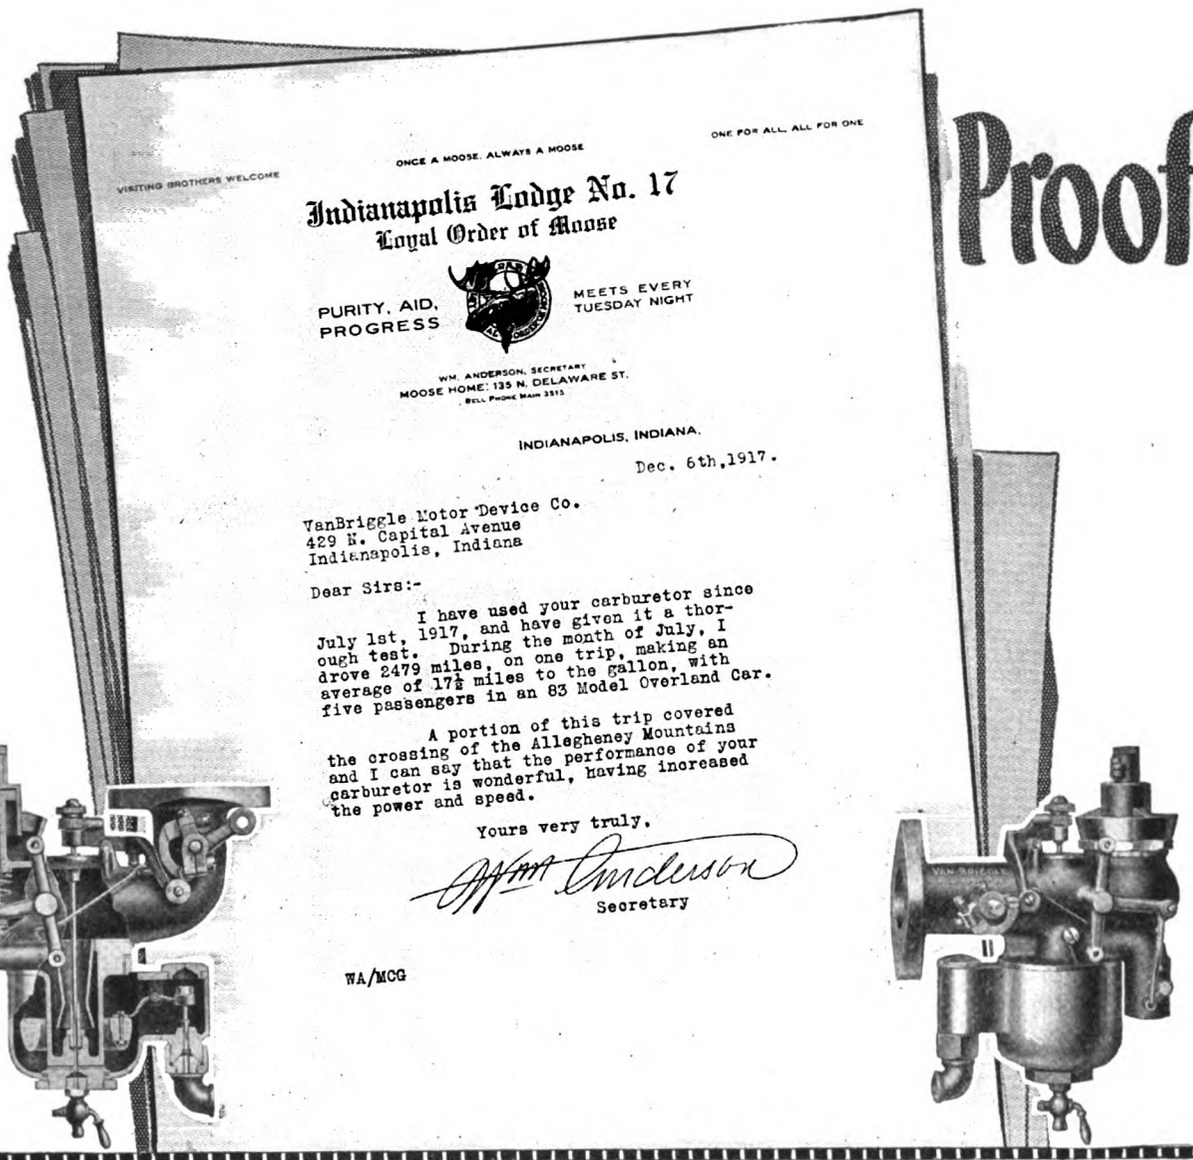
Your customers are not demanding a better carburetor—a better clutch—a better gearshift—or a better self-starter—what they are demanding is none of these devices at all, but emancipation from them.

Instead of demanding six or eight or twelve cylinder engines—what your customers really want is a smooth, safe, flexible ride—one-finger control. What they really want is comfort—safety—simplicity.

And they want a car whose fuel is kerosene.

If there is any advantage in selling your customers what they really are demanding—

If there is any advantage in delivering them the kind of performance they have always wanted in an automobile—



Then the franchise for the sale of the Stanley Steam Car in your territory is the best business asset you could get.

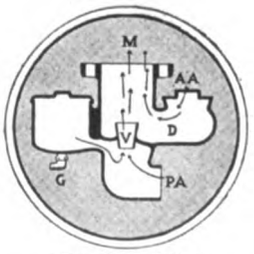
VAN BRIGGLE CARBURETOR

One Principle for all Motors

Here's written proof from Wm. Anderson, who, like all other VanBriggle users, has found through *actual* test, that the VanBriggle Carburetor *increases* power and speed, and *delivers* greater mileage—even under the most laborious circumstances. Illustrated descriptive booklet free on request. *Send for it.* ¶ JOBBERS AND DEALERS: The VanBriggle is as easily handled as tires. Small stock meets any need. New opportunity for profit and service. Write for proposition.

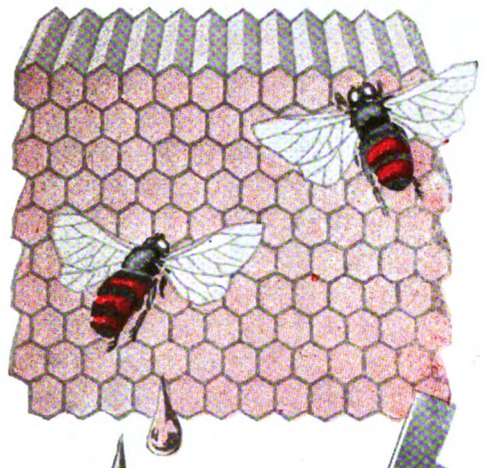


KEY TO DIAGRAMS: PRIMARY AIR (P.A.); AUXILIARY AIR (A.A.); GASOLINE (G); MANIFOLD (M.); MIXING CHAMBER (D.); VENTURI TUBE (V.); LOCATION OF MANIFOLD ON HORIZONTAL TYPE (Z.).

The Van Briggle Way

EXPLANATION OF DIAGRAMS

Because of the peculiar construction of the Van Briggle's primary air chambers, the primary air enters the venturi tube in a whirling, swirling movement, breaking even the poorest gasoline into the most minute particles. The primary mixture then enters the mixing chamber. The auxiliary air, traveling across to the manifold MUST PASS THROUGH THE PRIMARY MIXTURE. Two mixtures are thus assured in the Van Briggle Carburetor—each thorough and absolute. A thorough mixture and complete vaporization mean EVERYTHING to your motor. Compare the Van Briggle Way with The Other Way. There *is* a difference!



The Other Way

VAN BRIGGLE MOTOR DEVICE CO.

Columbia Storage Battery

With the honeycomb grid

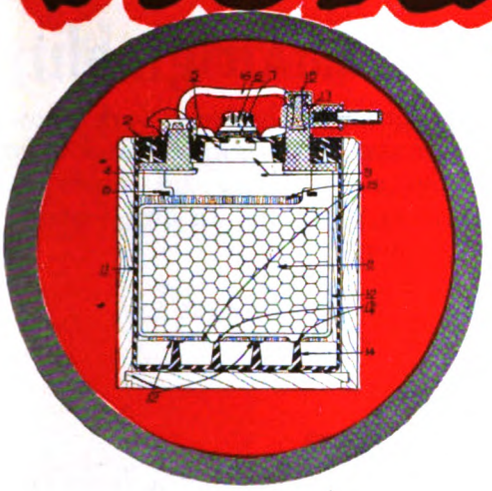
The hexagonal pattern of the honeycomb gives the maximum combination of strength and capacity. It gives greater support to the material enclosed than any other construction.

We have taken our tip from the honey-bee. In a cell which not only is the strongest mechanical construction, but which also holds its contents securely braced in every direction, the bee packs away his golden store of honey. In a grid of this same honeycomb construction, we pack away a golden store of profit for you.

For, realizing that the most vital part of a storage battery is the plates, we have so constructed the plates of the Columbia Storage Battery that they will back a real guarantee, a *definite* guarantee of capacity, performance, life, and service.

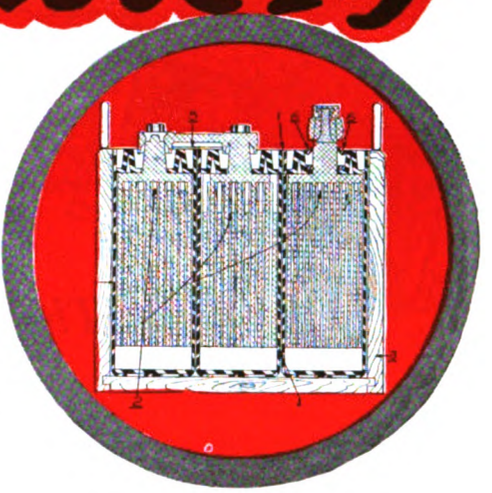
This design—exclusive to the Columbia Storage Battery—gives the maximum area of active material, the greatest and most uniform conductivity, and the greatest resistance to buckling for a given weight. This ability to withstand abuse comes from the hexagonal shape and the way the cells on opposite sides of the plates are "staggered," so that each side reinforces the other, and the active material interlocks in all directions.

You can see how this gives strength where strength is needed: the result is Service when Service is needed.



It is the ability of the Columbia Storage Battery to give continuous service, rather than continually *require* it, that makes a Columbia dealer an unusually profitable connection.

Our new plan of distribution is entirely different from the general scheme commonly followed. Our plan makes it possible for you to build up a highly profitable storage battery business without incurring the expense and investment of installing complete service station equipment and stock.



National Carbon Company, Inc.
Department R Cleveland, Ohio

Digitized by Google

Columbia Storage Battery

THE honeycomb grid described on opposite page is but one of 18 distinctive features, every one of which is a Columbia point, not merely of difference, but of *superiority*.

1. **Connector Skirt**—Automatic Capillary Seal holds the sealing compound in contact with post. Simpler, more permanent, more positive and effective than hard or soft rubber.

2. **Sealing Well**—Affords the maximum sealing surface from the interior of the cell to the exterior. No heavy, unsightly compound used. Smooth, neat appearing top.

3. **Acid Space**—Largest possible for restricted dimensions. Permits rapid radiation, quick cooling, and less frequent flushing or addition of water.

4. **Chilling Ledge**—Instantly cools compound when poured into sealing wells. This, with tight-fitting cover, prevents sealing compound flowing into cell. Eliminates one common cause of short circuits.

5. **Vent Plugs**—Bayonet catch design with ample grip, locks tight with simple quarter-turn, and prevents loss of electrolyte by splashing. Large hole permits easy inspection of plates, separators, and solution level.

6. **Vent Outlet**—Cannot become clogged with dust or other impurities or allow same to be washed back into cell. Location near base prevents any expelled electrolyte coming in contact with fingers.

7. **Vent Gasket**—Of soft rubber, prevents acid creeping or leaking.

8. **Separator Retainer**—Flat hard-rubber strip. Furnished in lengths which are simply pushed into position and snapped off with fingers. Cannot be dislocated to allow separators to float, causing short circuits.

9. **Honeycombed Grids**—An exclusive Columbia feature, gives greatest and most uniform conductivity and the greatest resistance to buckling for a given weight. Pellets interlock and the grid is reinforced in all directions. Great toughness, tensile strength, and ductility.

10 and 11. **Staggered Plates**—Positive elements are kept against one side of jar and negative elements against other. Separators fit jars tightly and extend beyond each side, top, and bottom edges of the plates, thus effectively preventing plate sediment from collecting across positive to negative plates at side and consequent short circuiting.

12 and 13. **Inclined Plate Feet**—Inclined feet force the plate against the edge of the cell. Holds this element rigidly in place, thus preventing breakage of jars, chafing, and destruction of separators.

14. **Four Jar Ribs**—The use of four ribs strengthens the jar at those points where the great resistance to shock is required. They also prevent short-circuit by accumulated sediment. (See 12 and 13.)

15. **Separators** fit jars tightly and extend beyond each side of the plate and beyond the top and bottom edges of the plate, thus preventing short-circuit due to buckling and short separators.

16. **Safety Handle**—Fastenings not exposed to corrosion. Will sustain 25 times weight required. Adapted to all standard type holddowns.

17. **Absolutely Universal Terminal**—Requires no lead burning or skill to set properly. To adjust is the work of a moment. No tools required. It is impossible to connect a Columbia Battery in a reverse direction. Because of the universality of the Columbia Terminal, only five types of Columbia Batteries are needed to make replacements on more than 300 different makes and models of cars.

18. **Clover Leaf Terminal Nut**—Designed to give an easy, firm grip of the fingers, and also to allow the use of pliers or a wrench without danger of damage.

Let us tell you about our new dealer and service plan which is entirely different from the general scheme of storage battery distribution. Makes it possible for you to work up a profitable storage battery business without expense of installing usual complete service station equipment and stock.

A Guarantee of Quality

Every car owner who buys Texaco Motor Oil by the can, with the seal unbroken, spends his money with the assurance that he will get his money's worth.

The Texaco green can with the red star on the sides is a guarantee of quality—when the seal at the end of the spout is unbroken.

TEXACO MOTOR OIL

is a quality oil. It is sold on the basis of quality, not of price.

The lubrication of a modern, high speed automobile motor is too important a factor for the lubricant to be *bought* on any other basis.

Texaco Motor Oil lubricates perfectly. It reduces friction to a minimum. It stands up well in use, retains its original lubricating qualities, because it prevents the leakage of gasoline into the crank case. Due to certain basic qualities it cannot deposit a hard carbon crust. It is the oil for *results*.

When you buy motor oil buy Texaco. The best way, the safest way, to buy is in one or five gallon cans. You can identify Texaco by its clear, clean color.

LIBERTY AXLES

SPECIFICATIONS

Ribbed axle and worm and gear housings cast from open-hearth steel. Also axle spiders which are bolted on each side of main axle casting. They also support the brakes.

Axle shafts are of chrome-vanadium steel, machined to 2¾ in. heat-treated and ground to size. Flange ¼ in. x 3½ in. holds bearings in shape and prevents axle from slipping sidewise.

Bearings: Two double thrust U. S. Ball Bearings on each axle, also two supporting the differential, U. S. Radial and Thrust Bearings at front and rear of worm. Sizes used have been tested and proved right in service.

Worm and gear of David Brown type. Worm of special alloy steel, gear of special bronze, both ground to size. Gear ratio 7¾ to 1.

M & S. Differential. Two-Piece housing of open-hearth steel. Special device holds worm gear in place.

Chrome-vanadium steel driving gears and pins. Brakes, dual double internal expanding, of our own design. Simple, effective, easily adjusted.

No truss rods—greater road clearance.

Spring centers as desired.

Track. Front 58¾ in., rear 61 in.

You Need These—Because They Mean More Business and Greater Profits

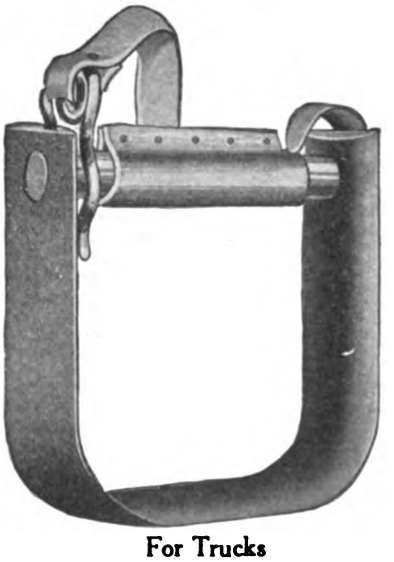
The Woodworth Easyon Chains and the Woodworth Easyon Solid Tire Grips make an instant appeal to the good sense of the motorist, and virtually sell themselves.

Woodworth Easyon Chains

Grip Like Mud Hooks
Ride Like Bare Tires

Are designed to be conveniently carried by the motorist and then to be quickly and easily put in place when he finds his back wheels spinning in the mud or snow or in any slippery place.
They take up scarcely any room.
They are applied in a few moments.
They provide perfect traction.
They are so designed that they cannot scratch the wheels or harm the tires.
They are made in three sizes—to fit any car.
They are packed 8 in a bag—4 for each wheel. Made also for solid tires—single and dual. They are low in price.

Chicago Distributors
Geo. B. Carpenter & Company
436 Wells Street



New York City Distributors
Rose Auto Supply Co.
1765 Broadway

Easyon Solid Tire Grip

Takes a powerful hold on the road; does not injure the tire or the roadway; it is practically unbreakable and causes no bumping on pavements. When run on hard road surfaces the tire is running over a very thin half oval surface, but when the tire slips the grip assumes a slanting position on the tire and takes a deep hold in mud or snow.

Made for all sizes of single or dual tires

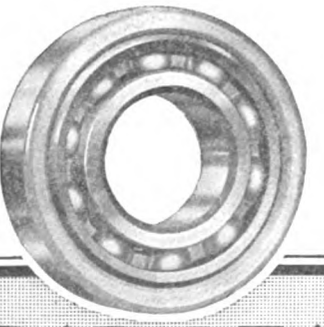
THE SCHATZ "UNIVERSAL" Annular Ball Bearing

Letters from users of the "Universal" prove that **it leads the field internationally** in **safety** and **carrying capacity** and that it **triumphs** over the **hardest** service conditions.

Takes **300%** to **400%** **more thrust load** than any other known annular bearing. Takes end thrust in **either direction without adjustment** and **without impairment of annular efficiency.**

"The Super Bearing"

INNER race one-third deeper than the average and held to curvature only 4% greater than the curvature of the balls.



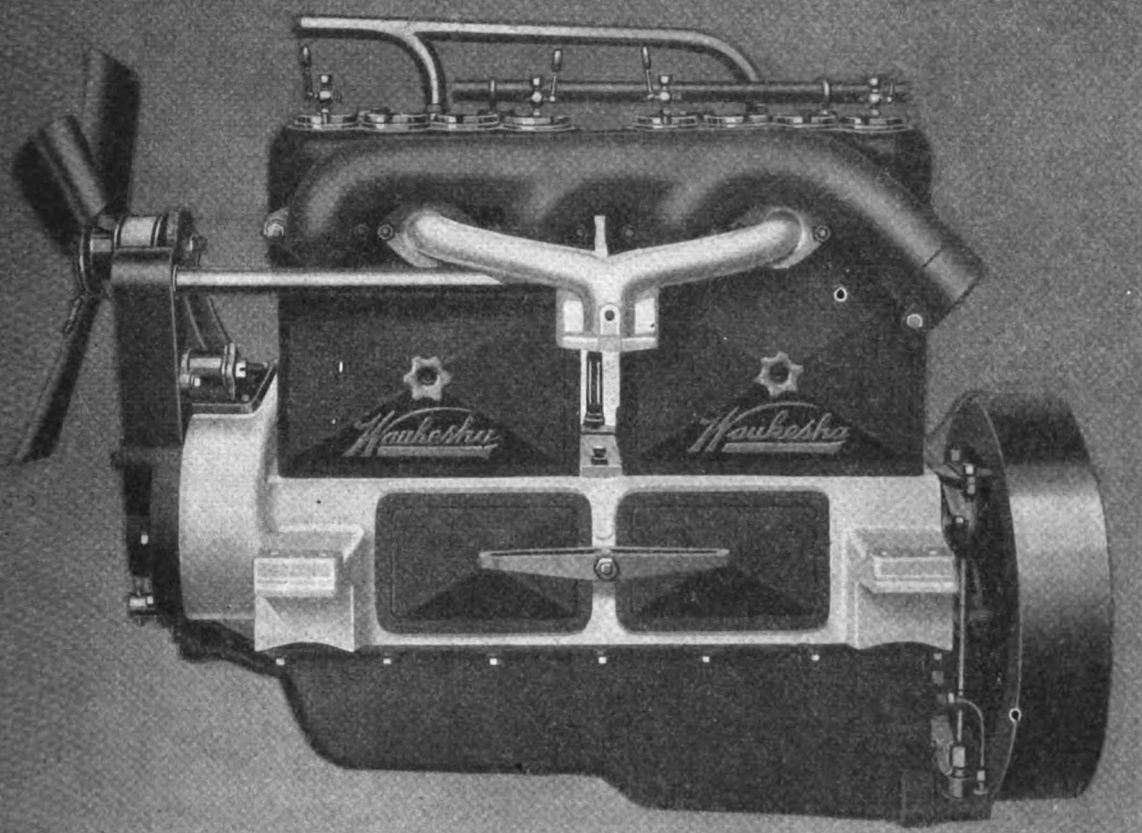
Outer race generated on two integral cups or race rings with space between to distribute radial load and to prevent binding strain under thrust load.

Separator free from rivets, rivet holes and distance pieces. It consists of two interlocking units and is sufficiently flexible to accommodate itself to changes in the axis of rotation of the balls.

Races and balls made from the highest quality of high carbon chrome crucible alloy steel to a specified analysis.

Raw material, parts in process and **finished product** are so rigidly and persistently inspected that the "Universal" has established a new standard of quality for ball bearing manufacture.

The "Universal" is a self-contained, combined radial and thrust bearing **internationally standardized** and **interchangeable.**



Engineers of motor cars and parts or of any other mechanism with rotating members should write for catalog and data sheets.

Where the Slightest Flaw Invites Destruction

IN the aeroplane—where the slighest defect in any part or material invites almost certain destruction and loss of life—you usually find Hess-Bright Ball Bearings. They are essential to machines in which dependability, endurance and faultless operation are imperative, and are invariably an indication of conscientious construction. The same is true regarding motor cars — the better are Hess-Bright equipped.

U. S. Patent No. 1,181,065

The Coffield Tire Protector
Eliminates Tire Troubles

See it at the New York Automobile Show
January 5 - 12, Booth 43, Fourth Floor

The Coffield Tire Protector makes an instant appeal to every automobile and motorcycle owner, for it is the last word in solving the tire trouble problem in pneumatic tires.

It is used by thousands of motorists in every state in the country. and every user is an enthusiastic booster.

Its Construction

The Coffield Tire Protector is made entirely of firm and elastic rubber, and does not contain a single thread of fabric. This makes it absolutely different from any similar device ever placed on the market.

It is made by hand with extreme care, and can never creep nor buckle inside the casing. On sweltering hot days it keeps the tire several degrees cooler.

Increases Mileage

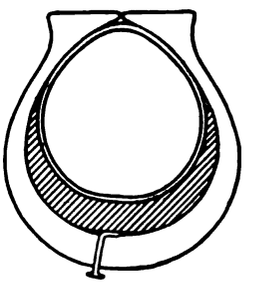
In addition to turning down nails, tacks, etc., before they can puncture the inner tube, the Coffield Tire Protector prevents stone bruises by distributing the blow so that it is taken up by the entire casing. This does not permit the fabric, which is the backbone of the casing, to become weakened at any one point.

Blow-outs are therefore reduced to a minimum, and the life of the tire is greatly increased.

Many users of the Coffield Tire Protector get 100% more mileage from their tires than formerly. Some get as high as 150%.

No Advance In Prices

In spite of the high cost of crude rubber, the price of the Coffield Tire Protectors has not been advanced. The first cost is low, and it is the only cost, for you only buy them once—and with proper use they will outlast many sets of tires.



Write to-day for descriptive literature. Or, see us at the New York Automobile Show—Booth 43, Fourth Floor.

State Agencies Open

We still have a few choice state agencies open for high-grade distributors.

The Coffield Tire Protector Co.
Dept. 300 Dayton, Ohio, U. S. A.

Perfect Protection

When a nail is picked up it is clinched between the Protector and the casing, thus preventing puncturing of the inner tube.

Shocks from stones, etc., are distributed around the casing. There is no weakening of the inside fabric at any one point.

Read What Users Say

An Aeroplane Engineer

I have been using your Tire Protectors for the past year, and have found them very satisfactory in the hottest of weather; and have made some special heat tests, finding that there is no heating or chafing of casing or tube. In one instance I got 15,400 miles from one casing by using the Coffield Tire Protector.

JOS. E. BUTZ, The Dayton-Wright Aeroplane Co., Dayton, Ohio.

A Prominent Banker

I am pleased to advise you that I have used the Tire Protectors you sold me last spring with a great deal of satisfaction. During the time they have been in use I have not had a puncture, and in addition to this great convenience I believe I have received at least 2,000 additional miles from my tires on account of the Protectors.

H. H. THOMAS,
V.-Pres., Savings Investment & Trust Co., East Orange, N. J.

A Lumber Company

It is poor economy for any motorist to be without Coffield Tire Protectors. If I owned a dozen cars I would have them on every wheel of every car, and save many dollars thereby. If the Protectors have any faults whatsoever, I have failed to find them.

I have more and better tire service at less expense. One of my tires has run about 1,000 miles since it was decided worthless, and it appears as if it may yet run another 1,000 miles.

N. W. CHURCHILL,
Yard Foreman, North End Lumber Co., Tacoma, Wash.

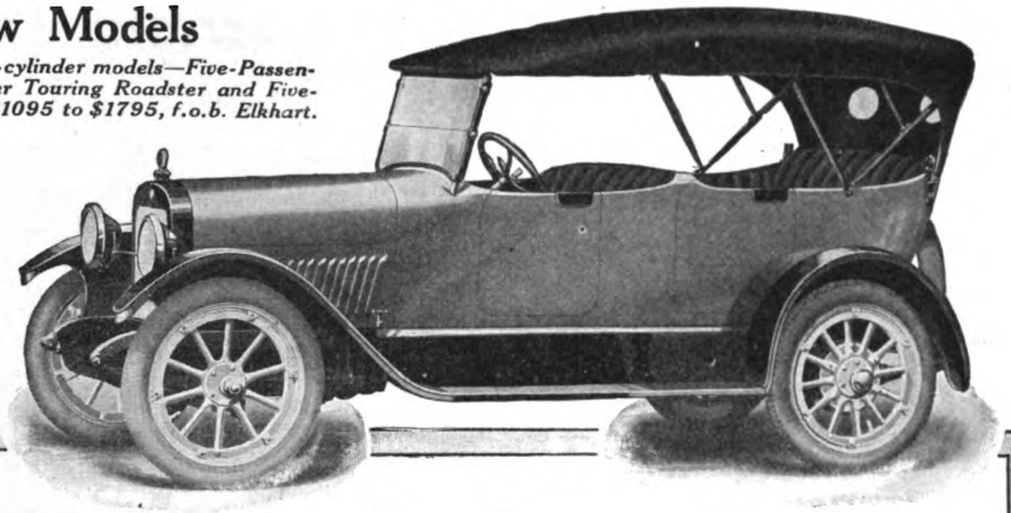
A Transfer Company

Replying to your inquiry regarding your Tire Protectors, will say they have given perfect satisfaction. We have not had one puncture since we have installed them, and can recommend them to anyone as a positive proof against punctures. They have eliminated our tire troubles.

PEORIA BUS & BAGGAGE LINE,
Peoria, Ill.

A Clothing Store

When you installed a set of Coffield Tire Protectors in our delivery car about six weeks ago we promised to let you know what we thought of them. Up to the present time we have not had a single puncture or a minute's delay or trouble of any kind.



Before putting your Protectors in the tires we had almost daily punctures and tire trouble —often two punctures in a day.

HENRY HALLE & BRO.,
Memphis, Tenn.

Six New Models

Three 4-cylinder models—three 6-cylinder models—Five-Passenger Touring Car, Four-Passenger Touring Roadster and Five-Passenger Sedan. Price range, $1095 to $1795, f.o.b. Elkhart.

Looks good, doesn't it?

—and the picture doesn't begin to do it justice

ELCAR

It is graceful in design and beautiful in finish—smart and stylish in every detail. Nothing lacking for beauty, comfort, performance or endurance. Drive all day and you won't be cramped or tired.

The steering is the easiest; the control the simplest. Easy riding whether fully or partially loaded; remarkable in this respect. Abundant power for hard pulls—fine driving qualities at all speeds—and all the speed you want.

Reliable quality is a certainty in the Elcar. We learned to put in quality years ago when building cars selling up to and above $3000. It is a quality car at a popular price—good and large enough to fulfill any motor car requirement.

Catalog on Request

Write for the Elcar catalog—very descriptive, well illustrated—gladly mailed to all interested.

Don't think of choosing until you have seen the Elcar. It will be at the New York and Chicago shows, and at other leading shows—or see it in the show room of any Elcar dealer.

Elkhart Carriage & Motor Car Company
C-778 Beardsley Avenue **ELKHART, INDIANA**

Pretty as a picture from any angle

Brief Mention of Elcar Points

Four-cylinder models, 37½ horse power at 2,100 r. p. m. Six cylinder models, 40 horse power at 2,100 r. p. m. Two unit electrical system. Long wheel-base, 116 inches; road clearance 10½ inches. Full floating rear axle with spiral bevel driving gears. Timken Roller Bearings front and rear. Double universal drive; tubular propeller shaft. A wonderfully easy riding semi-elliptic spring suspension. Roomy and comfortable bodies of beautiful design and durable finish; new "Cathedral Pipe" upholstering. Equipment complete, even to motometer.

Dealers! Look at the value—look at the price—then get in touch quick if you are interested. Our increased production will enable us to accommodate a few more live dealers in picked territories.

"KNOWING HOW SINCE '81"

Maxim Silencer
Is a Valuable Selling Point for Any Car

To the Passenger Car Manufacturer:

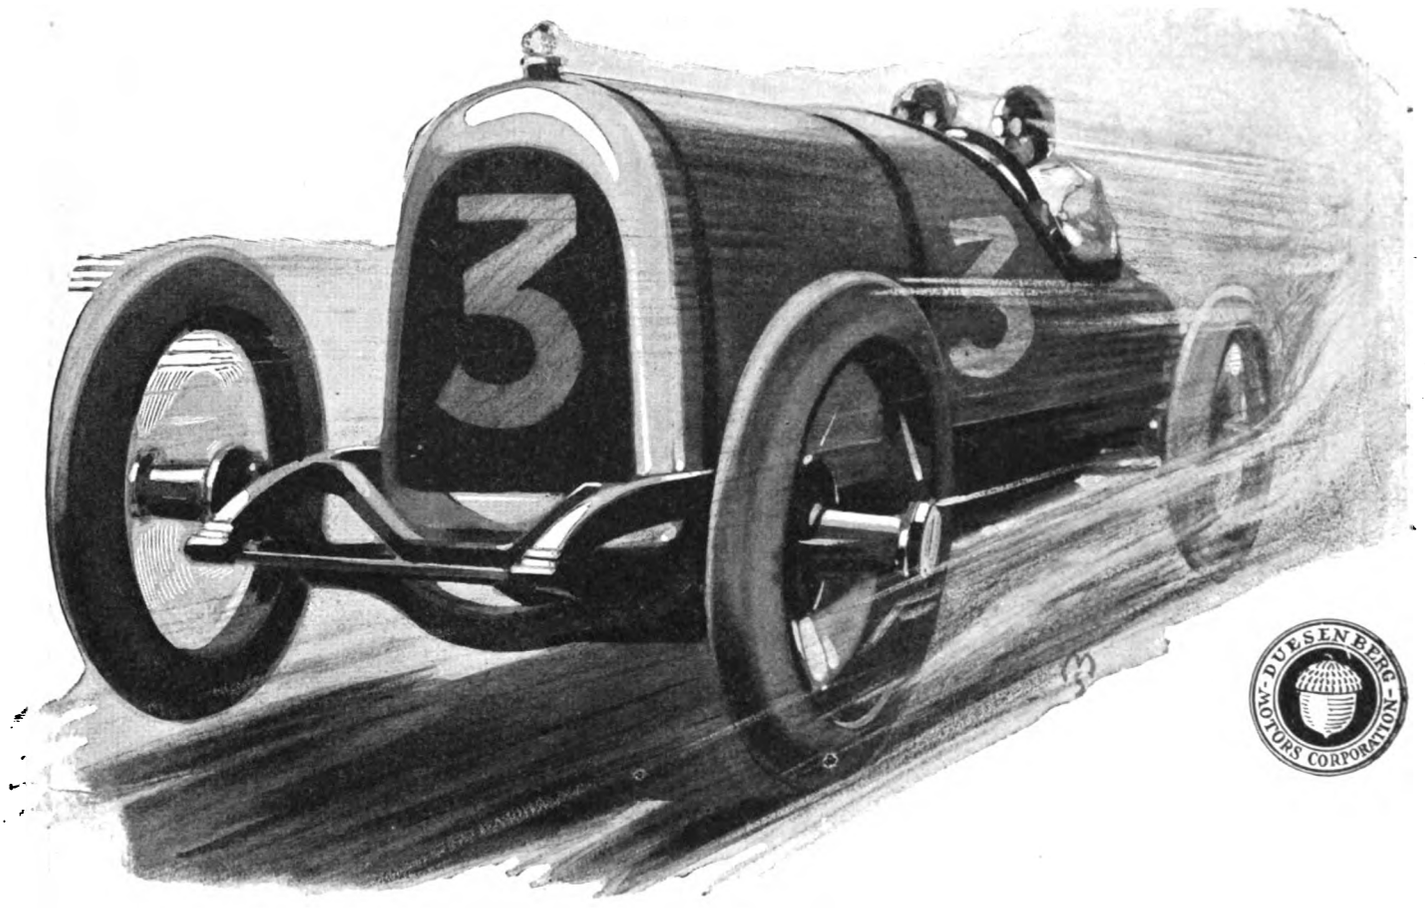
The dealer who can point to the car he sells, and say to his prospective customer: "This car is equipped with a Maxim Silencer," has brought forth a new and forceful selling point.

H P. MAXIM
Inventor

The fame of Maxim Silencers for fire arms has built a reputation that extends far beyond the following that has actually used the Silencer. Around this reputation, great prestige and confidence have grown up.

Maxim Silencers for automobiles are proven selling points that sell. They insure noiseless motors, free from power hampering back pressure.

As manufactured by Geuder, Paeschke & Frey, Maxim Silencers are now available for motor cars of every make.



Let us submit a quotation on your requirements

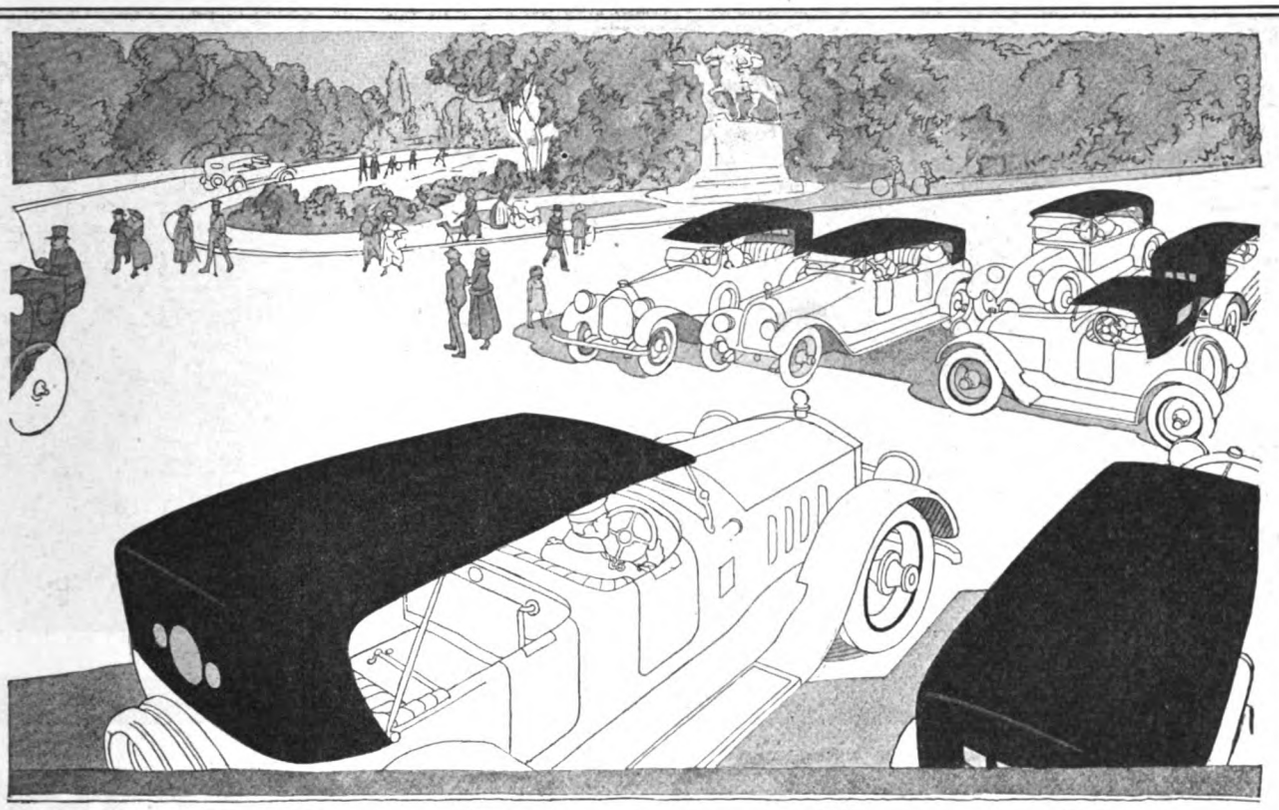
EDDIE HEARNE'S GREAT RECORD

Duesenberg Automobile Engines have quite a reputation of their own for tremendous power, high efficiency and dependability, but the Duesenberg Engine in Eddie Hearne's "Roamer-Duesenberg Special" is a world-beater for sheer, downright grit and stick-to-it-tiveness. Hereunder is a brief resume of Hearne's record this year:



Nov.	29th, Ascot Speedway, Los Angeles, 50 miles	First
Oct.	29th, Uniontown Speedway, Uniontown, Pa., 168½ miles	First
Oct.	13th, Fair Grounds, Richmond, Va., 5 miles	First
Oct.	13th, Fair Grounds, Richmond, Va., 10 miles	First
Oct.	13th, Fair Grounds, Richmond, Va., 25 miles	First
Oct.	6th, Fair Grounds, Danbury, Conn., 5 miles	First
Oct.	6th, Fair Grounds, Danbury, Conn., 10 miles	First
Sept.	28th, Fair Grounds, Trenton, N. J., 5 miles	First
Sept.	28th, Fair Grounds, Trenton, N. J., 10 miles	First
Sept.	28th, Fair Grounds, Trenton, N. J., 10 miles	First
Sept.	22nd, Sheepshead Bay Speedway, 100 miles	Third
Sept.	3rd, Uniontown Speedway, Uniontown, Pa., 112½ miles	Finished
Sept.	15th, Narragansett Park Speedway, Providence, R. I., 25 miles	Fourth
Sept.	15th, Narragansett Park Speedway, Providence, R. I., 100 miles	Third
July	14th, Twin Cities Speedway, Fort Snelling, Minn., 100 miles, out 17th lap.	
July	4th, Omaha Speedway, Omaha, Neb., 150 miles	Fifth
June	16th, Chicago Speedway, Chicago, Ill., 250 miles	Fourth
May	30th, Cincinnati Speedway, Cincinnati, O., 250 miles	Fifth
May	10th, Uniontown Speedway, Uniontown, Pa., 112½ miles	Third

This is the complete list of races in which Hearne started this season as supplied by the American Automobile Association. It is a record unique for its remarkable showing of consistency and speed.

IN fact, smart tops are necessary to make smart cars. The truth of this is readily apparent if you will look at the cars on the avenue and measure with your eye just what you see. In a majority of instances, you will see the top first, and in all cases where the top is raised, it is the most prominent part of the car.

It is this *importance* of the top that has led nearly fifty manufacturers of good cars to adopt Neverleek Top Material as regular equipment. They have found by experience, testing and observation, that Neverleek makes not only smart tops but good tops. Neverleek tailors well; that is, it takes faithfully the lines and curves of good designing; it forms a top that is a harmonious part of the whole car.

The beauty and richness of Neverleek *are lasting*. This material has quality in it; the stuff that not only guarantees protection against leaking but retains good looks through long wear. Neverleek won't stretch nor sag nor crack nor fade.

Remember this one point when you buy a new car. Any car is a better car if the top is Neverleek. It will be a better-looking car as long as you have it and a higher selling value when you dispose of it.

Nearly fifty makes of cars, selling from less than $1000 to more than $5000, carry Neverleek Top Material as regular equipment. This list is given on the left of this page. Study it. We have a booklet, "Style in Motor Tops," containing information that will be interesting to any motorist and samples of material showing different grains and finishes. Why not write for it today? Mailed free on request. Should the condition of the top on your old car suggest renewal, any top-maker will be glad to re-cover it with Neverleek.

PARKER PROCESS
RUST-PROOFS IRON AND STEEL

Steel-so hard to get so easy to save!—

Now being used in the Manufacture of

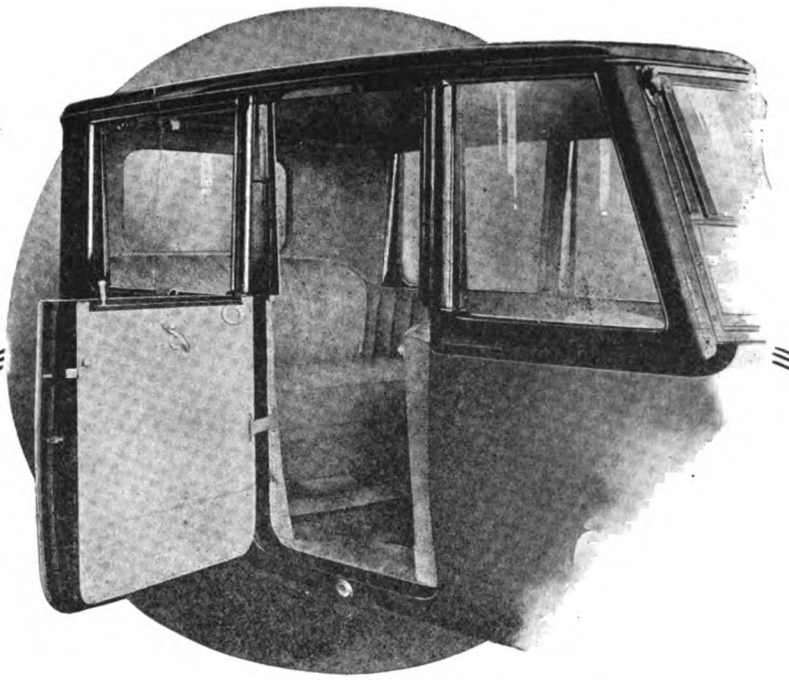
Typewriters
Building Supplies
Automobiles
Motor Trucks
Motor Accessories
Electrical Equipment
Farm Implements
Ranges and Stoves
Steel Furniture
Sporting Goods
Phonographs
Dental Supplies
Railway Supplies
Telephone Equipment
Ornamental Iron Work
Arms and Ammunition
Etc., etc.

Think of the millions of dollars invested in the steel industry—bringing the ore from the mine—refining it in the mammoth smelters. And the hundreds of thousands of men employed!

Then think that 23% of all of this valuable metal is allowed to rust away each year! It is almost unbelievable. The waste is so stupendous that the human mind can hardly fathom it.

When it might be prevented if iron and steel products were only protected properly against this rust. There is now a satisfactory method of rust-proofing iron and steel—the Parker Process.

This method is being employed today by over five hundred of the leading manufacturers of the country. The value of it—the absolute reliability of the results—cannot be questioned when so many of the great industrial authorities endorse it.



The Parker Process can be fitted into your production plans. It does not interfere with efficiency—is not prohibitive in cost. It is extremely practicable—because it is not electrical, a paint, or a coating of any sort.

We would like to tell you more about the Parker Process. Also we will gladly perform any experiments you may desire to show that it is practicable for your particular product. Furthermore, our plant is open for any inspection to anyone interested in the protection of rust. You will be welcomed at any time.

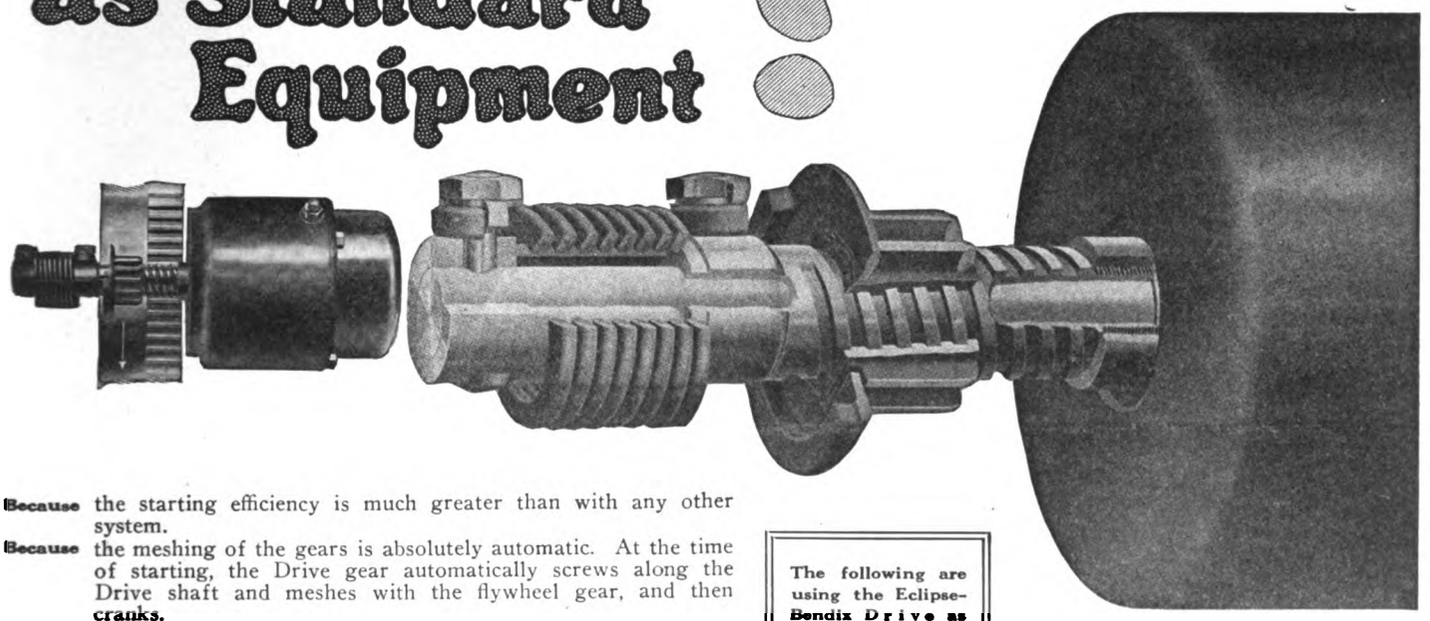
RAYFIELD CARBURETOR

Hooverizing on Gasoline

YOU don't relish a half-baked potato; and it has little nourishment. Improper cooking wastes food.

Half-consumed gasoline—from improper carburetion—is likewise waste. It goes up in vile-smelling, black smoke which marks the inefficient, extravagant car.



We're all "Hooverizing" these days. We must conserve fuel as well as food. The Rayfield Carburetor will get every possible ounce of power out of your gasoline.

We guarantee this: 20% to 50% more miles per gallon and better all-'round performance. You can test a Rayfield on your car; cold weather is a good time. If you're not convinced, we'll gladly refund your money.

Findeisen & Kropf Mfg. Co.

Why have 150 Car Builders adopted the ECLIPSE-BENDIX DRIVE as Standard Equipment?

Because the starting efficiency is much greater than with any other system.

Because the meshing of the gears is absolutely automatic. At the time of starting, the Drive gear automatically screws along the Drive shaft and meshes with the flywheel gear, and then cranks.

Because the demeshing after starting is absolutely automatic. After the engine is started the flywheel gear turns faster than the Drive gear and screws the latter back on the Drive shaft until it is out of mesh.

Because cast iron teeth without any chamfer not only make a great saving in cost, but are actually superior, being the simplest, most efficient and durable construction possible. The teeth are cut in the flywheel which is a natural gear blank. Stripping of these teeth by accidental starting when the engine is running is impossible, because of the automatic demeshing action.

Because back-fires are automatically protected by the shock-absorbing spring Drive.

Because there is no over-running clutch to stick or slip.

Because there is no resistance or two-point switch to burn out.

Because there are no shifting levers and pedals, with their complications.

Because it is simpler and has fewer parts than any other starting system.

Because it eliminates chains, which stretch, break and get noisy.

Because it minimizes gear noise in cranking by driving through a spring.

Because it is absolutely silent when the engine is running, being absolutely disconnected.

Because it permits of using a simple, small generator for constant running.

Because it permits of cranking the engine with the most efficient of all starters—a separate electric starting motor—and also more evenly.

Because it makes the two-unit type of starting and lighting system superior to any other and the most popular of all.

Because it requires the minimum of care and attention during the life of car.

Because it is regularly supplied and used as standard equipment with the following starting and lighting systems, on over 150 different makes of motor cars; and also on a large number of marine and aeroplane motors.

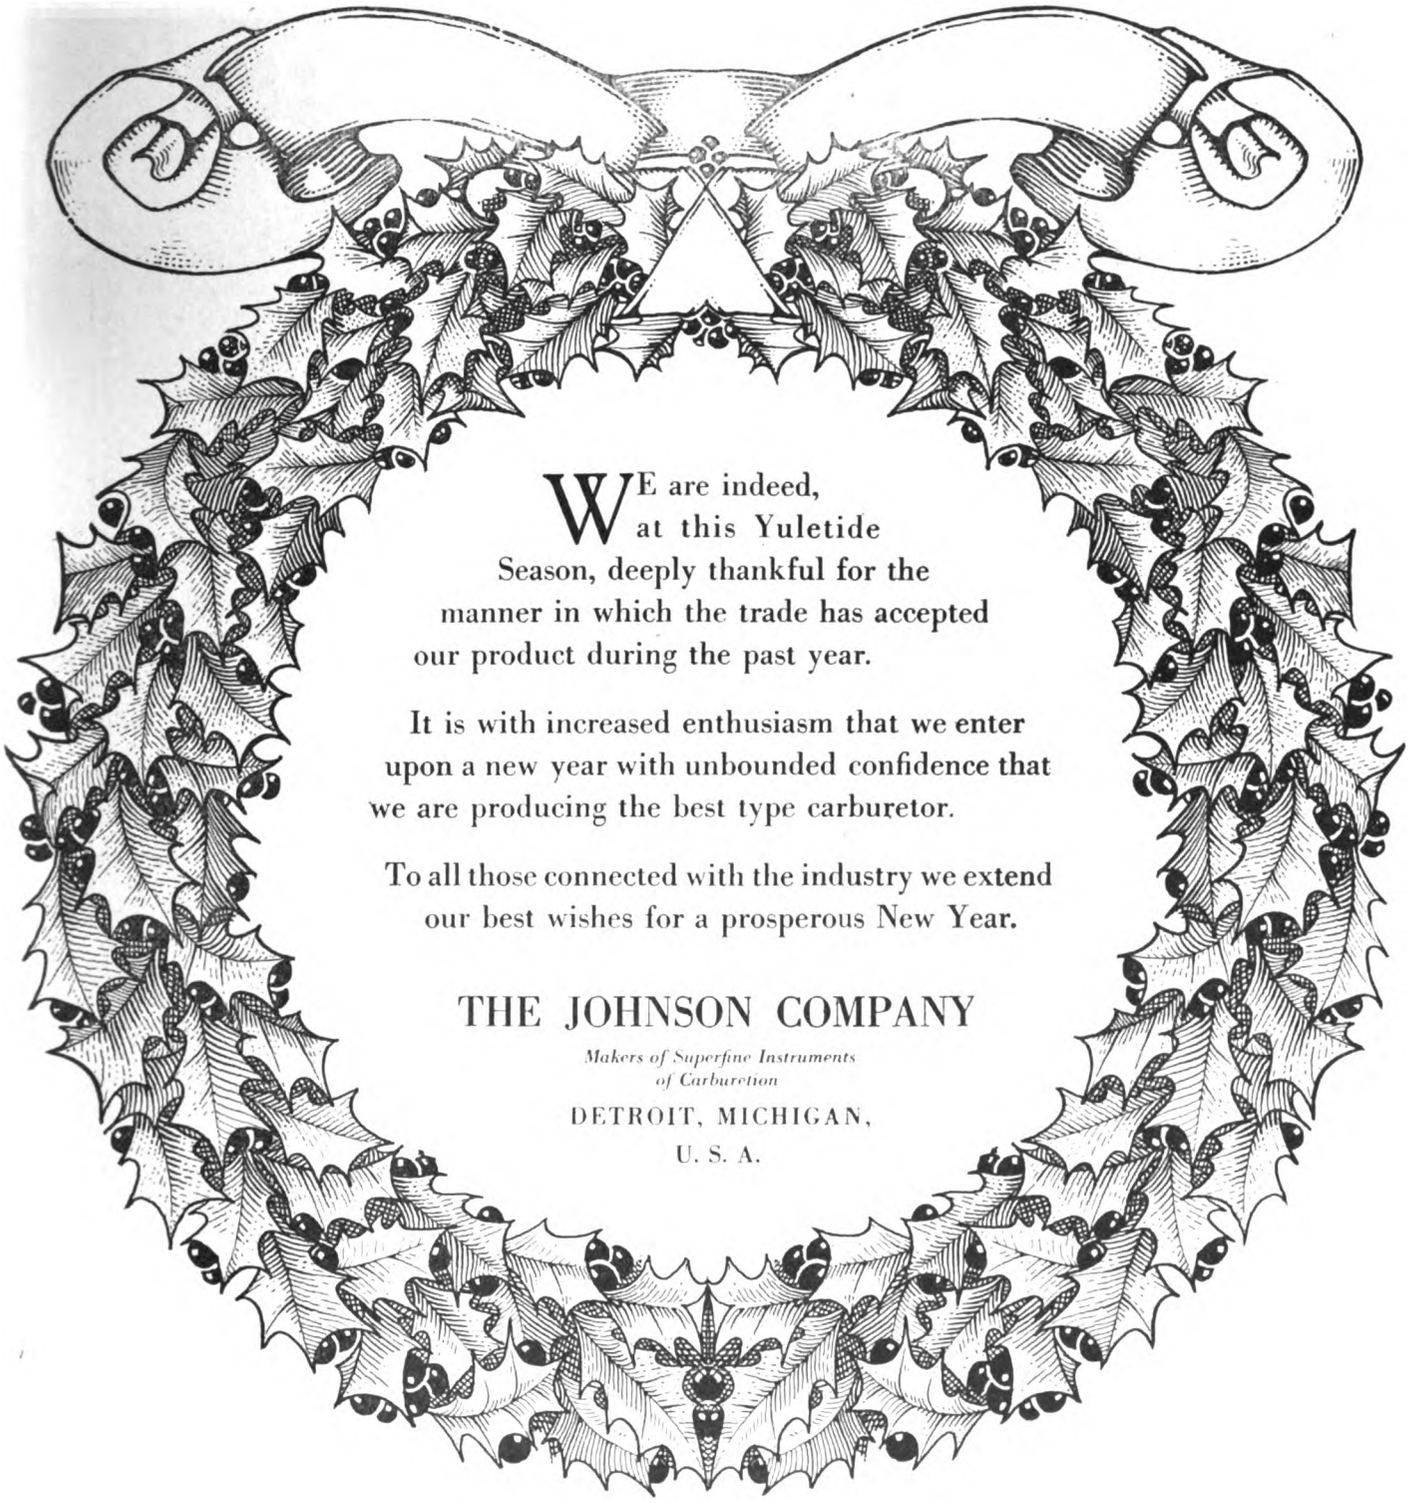
DURABILITY is the essential quality often looked for in top material but rarely found. When Drednaut is used, an unequalled, weather-resisting, long-wearing top shields you.

More "Chase" material is used on vehicles today than any other brand.

DREDNAUT MOTOR TOPPING often outlasts the car itself—it is a positively *weatherproof*, non-cracking, non-blistering material that can be easily handled and cleaned.

APPEARANCE is a big factor in top material. A top of Drednaut adds beauty to any car,—the beautiful, rich-appearing surface is not impaired by folding or the elements.

Use DREDNAUT and *be protected*, both by a splendid top and the "CHASE" name.



DREDNAUT MOTOR TOPPING retains its smart appearance after years of the severest use—it is a *genuine* product, that has given complete satisfaction the past twenty years.

TORBENSEN INTERNAL GEAR TRUCK DRIVE

Now Buyers Ask— "Which Rear Axle—and Why?"

A careful study of the newest motor truck statistics shows clearly the indisputable leadership of internal gear drives among motor truck buyers.

This is because actual truck service has shown them that the final drive is the most important feature in making a truck reliable or otherwise.

Now there are 44,257 Torbensen Internal Gear Drive axles in use. Torbensen Drive is by far the leader of all internal gear drives.

This leadership is due, for the most part, to the patented, forged-steel I-Beam — exclusive in Torbensen Drive — which makes it stronger, lighter, more economical and longer-lasting.

It has become the strongest selling feature in trucks equipped with it.

The splendid seventeen-year record of Torbensen Drive gives all the proof that any one can ask for.

Torbensen Advertising is made to help you sell trucks. It is running steadily in the big national weeklies. Tie up with it by handling a line of trucks that have Torbensen Drive.

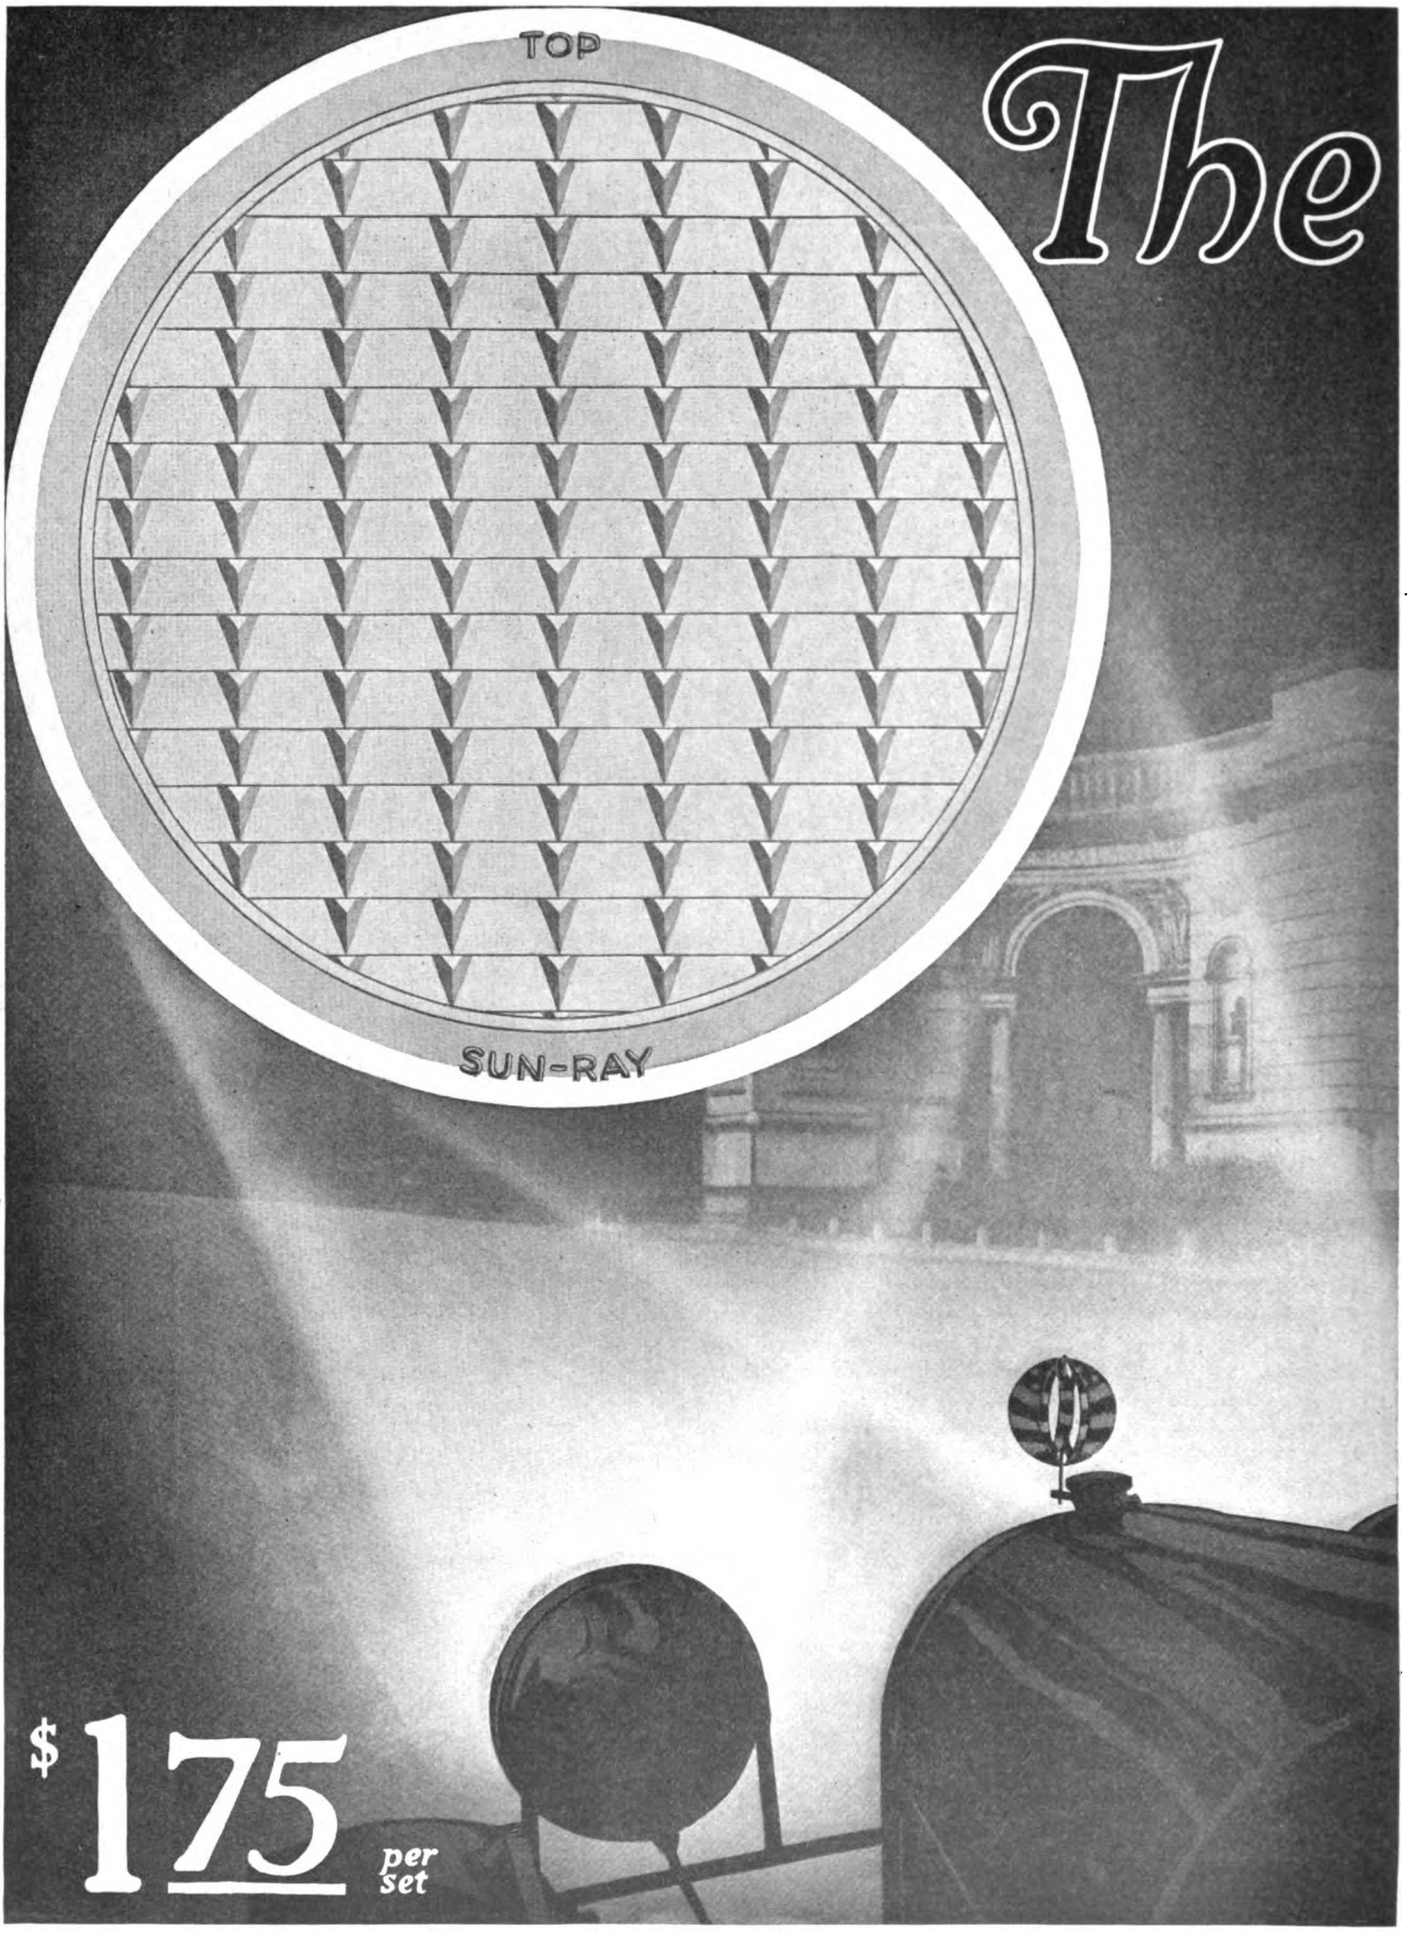
Write now for the instructive booklet—"Driving *at* the Wheel and *near* the Rim." It tells all about Torbensen Drive frankly and factfully.

A solid-forged I-Beam is the unyielding steel backbone of Torbensen Drive. It carries *all* the load. It does *nothing* else.

A jackshaft with pinions on its ends does *all* the *driving* through the internal gears. It does *nothing* else. It carries *no* load whatever.

These members, held in practically perfect, permanent alignment, form the famous Torbensen Drive.

This drive is as simple as any good drive can be. All its parts are easily accessible. It is easy to take apart and easy to put together again.



Seventeen years of ever-growing service have *proved* that Torbensen Drive makes trucks last longer, makes rear tires give 20% greater mileage and reduces gas and oil consumption.

THE TORBENSEN AXLE CO.
CLEVELAND, OHIO

TORBENSEN DRIVE is made to last. Every owner gets a GOLD BOND GUARANTEE that the I-Beam axle and spindles will last as long as the truck and the internal gears at least two years.

At Last!

A popular priced lens that meets every legal requirement

EVER since automobile headlight lenses were put on the market the motoring public has been forced to pay extraordinarily high prices for them—prices out of all proportion with the cost of producing the lenses themselves.

But here is a new lens—the Sun-Ray—that gives you everything the other lenses give and more. It is manufactured by the most approved methods and from the best materials—yet it sells *profitably* at $1.75 a pair.

All the other lenses can be grouped in two main classes. One class diffuses light, the other class deflects or refracts it.

The diffusing lens takes the strong light rays from the reflector and scatters them in all directions, making a wide area as light as day in front of your car.

By its very nature it precludes the possibility of a sharp, bright penetrating *distance beam.*

The refractive or deflective lens gathers up all the light rays and redirects them down in a *concentrated narrow beam on the road*—a beam so narrow as to make night driving dangerous since both sides of the road are dark and turning is therefore hazardous.

It was with a full knowledge of these deficiencies that we entered the field determined to produce a lens that would prove *truly effective.* At the same time we determined to market our lens at a fair price to the public, with a fair profit to ourselves and our selling agencies.

The result is the Sun-Ray lens—priced at $1.75.

It gives motorists for the *first time* a lens that *both* diffuses *and* refracts the light. It shoots a long concentrated beam of road light far ahead, showing every inch of the highway. And it does *more.*

It gives you a side diffusion *of 168 degrees,* lighting up ditches, curves, crossroads and signs.

It gives you all the advantages of diffusion *plus* the advantages of deflection and meets the complicated legal requirements of every State in the Union. The Sun-Ray distance beam is the necessary 42 inches above the road at a distance of 75 feet ahead of the car. This distance beam, which is bound to rise and fall with the irregularities of the road, does not glare.

The hard, biting horizontal beams are *partially broken up* by a number of thick triangular prisms on the inside of the glass. This feature, in addition to giving tremendous side diffusion minimizes glare without in any way interfering with the effectiveness of the road light.

The clear parts of the Sun-Ray light are thin, thus reducing the absorption common to the thicker lenses —and the outside surface is absolutely flat and smooth, preventing dust, snow and mud from collecting on the glass and dimming your light.

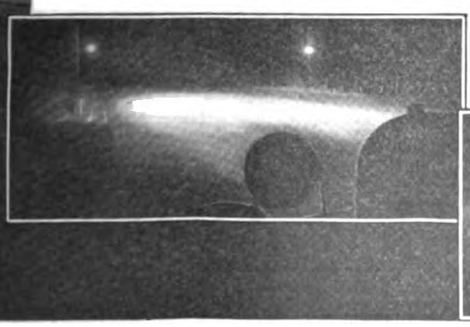
Consider all these advantages. Then consider the price of the Sun-Ray—*just $1.75 per pair.*

The field that such a lens, at such a price, opens to dealers is tremendous—and constantly growing.

We want jobbers in every important center in the United States. We want dealers in every community. Write or wire at once for territory.

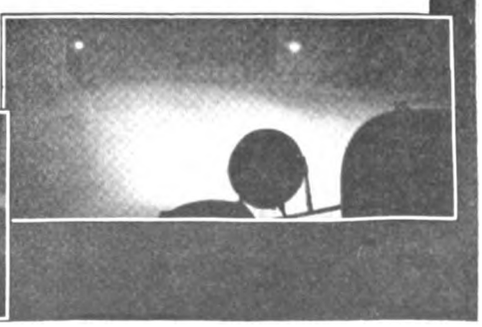
THE PRISMOLITE CO., 4th and Gay Streets, Columbus, Ohio

Every size for



$1.75 per set

25c additional west of the Missouri River.



The Sun-Ray lens combines the advantages of both the diffusive and refractive types.

The refractive type of lens sacrifices diffusive side lighting for a bright beam of light concentrated on the road.

The diffusive lens gives wide side lighting but its very construction precludes the possibility of a bright "distance beam."

The Square Path of Light

Twice the Lighted Area

Why You Will Want to Sell the Dillon Lens

The ideal lens is here at last! Not a lens in name, but a lens in fact. Not a mere piece of pressed glass hurriedly marketed to fill a need nor a lens with only fantastic design to distinguish it.

But an actual **lens**—the Dillon Multi-Vision Lens—distinguished by its **performance!**

The Dillon Multi-Vision Lens embodies new scientific principles of illumination. Other lenses cut out glare and cut down light. The Dillon actually **adds** to your field of vision while eliminating glare, because it projects a **square** path of light instead of a narrow, wedge-shaped beam. Thus, the Dillon Multi-Vision Lens is safe, shadow-free, and glareless. **It does what others claim to do,** yet it costs **less** than many inferior makes. It is easier to handle and easier to sell. All sizes are sold at the same low price, $3.50, **anywhere** in the United States.

Dillon demand is growing, Dillon sales are mounting, Dillon dealers will profit.

Millions Will Read

Thousands Will Buy

How We Are Helping You Sell the Dillon Lens

The Literary Digest carries a double-page advertisement, December 29th, shown above. This is the opening gun of a barrage of publicity, sure to create a strong "drive" on lenses. This extensive advertising campaign will cover the country in such publications as the Digest, Collier's, Scientific American and other weekly and monthly journals.

It is not, however, the volume but the **method** that makes Dillon advertising novel. **YOU** will be selling every Dillon prospect because you, Mr. Dealer, will be featured in every advertisement, through the introduction of an original trade character—**Otto Deeler.**

OTTO DEELER

Thus, attention will be focused on your store in a new and refreshing manner. This idea alone will be worth thousands to Dillon dealers.

Write for special proposition. Learn to-day of the many selling helps we give you.

Crawling under axle to place jack with hands

Placing and operating jack without even reaching under car

The Safest, Cleanest and Most Powerful Auto Jack Made

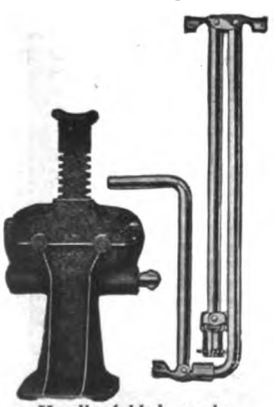
A woman can handle a Rees Jack with ease, and without even soiling her hands.

It can be placed under the car by its long handle, thus obviating the necessity for reaching under the axle to place it with your hands.

You can *stand up* when operating it. It will operate with the handle at an angle to the jack, which is sometimes necessary on uneven or muddy roads.

CONVERTS FRICTION AND END THRUST INTO POWER

Being a worm-drive jack (the most efficient lifting principle known to mechanics) it lifts *steadily*, not in jerks. It cannot run out when held upside down. It cannot fall under a load.



The Rees Jack is no larger nor heavier than other jacks—it fits in your tool box, handle and all.

But it is tremendously powerful. Born and developed in railroad yards, lifting freight cars, an automobile is *merely play* for it. You can lift a car with one finger on the jack handle.

ONLY FOUR WORKING PARTS

It is simple and compact in construction. Contains only 4 working parts, no springs, pawls, or ratchets. Handle is connected to jack by universal joint, and can be locked or unlocked by one twist of the fingers.

$8.00

Handle folded, ready for tool box

THE UNITED STATES JACK COMPANY NOW OWNS THE EXCLUSIVE SELLING RIGHTS FOR THE REES JACK

DEALERS

The Rees Jack sells itself. It is one of the best advertisements and attention-getters you can have in your place.

Everyone who sees it wants to try it. And one trial means a sale, if the one who tries it has any use at all for a jack. Let them try it on your office safe. It will lift it without an effort.

Write at once for extremely generous and certain business-getting proposition. Big profits, small outlay, quick sales.

Russel Features

The power axle is entirely independent of the load-carrying axle, wholly relieving it of road and load strains.

The load-carrying axle is a one-piece round bar of heat-treated chrome nickel steel.

The Russel Differential, Internal Gears and Pinion Gears are made in our own machine shops guaranteed by Russel reputation.

Russel brakes are exceptionally large and afford unusual protection to the truck on the crowded thoroughfare and steep grade.

Less complicated parts.

More efficient and reliable under all conditions of road or load.

More ground clearance.

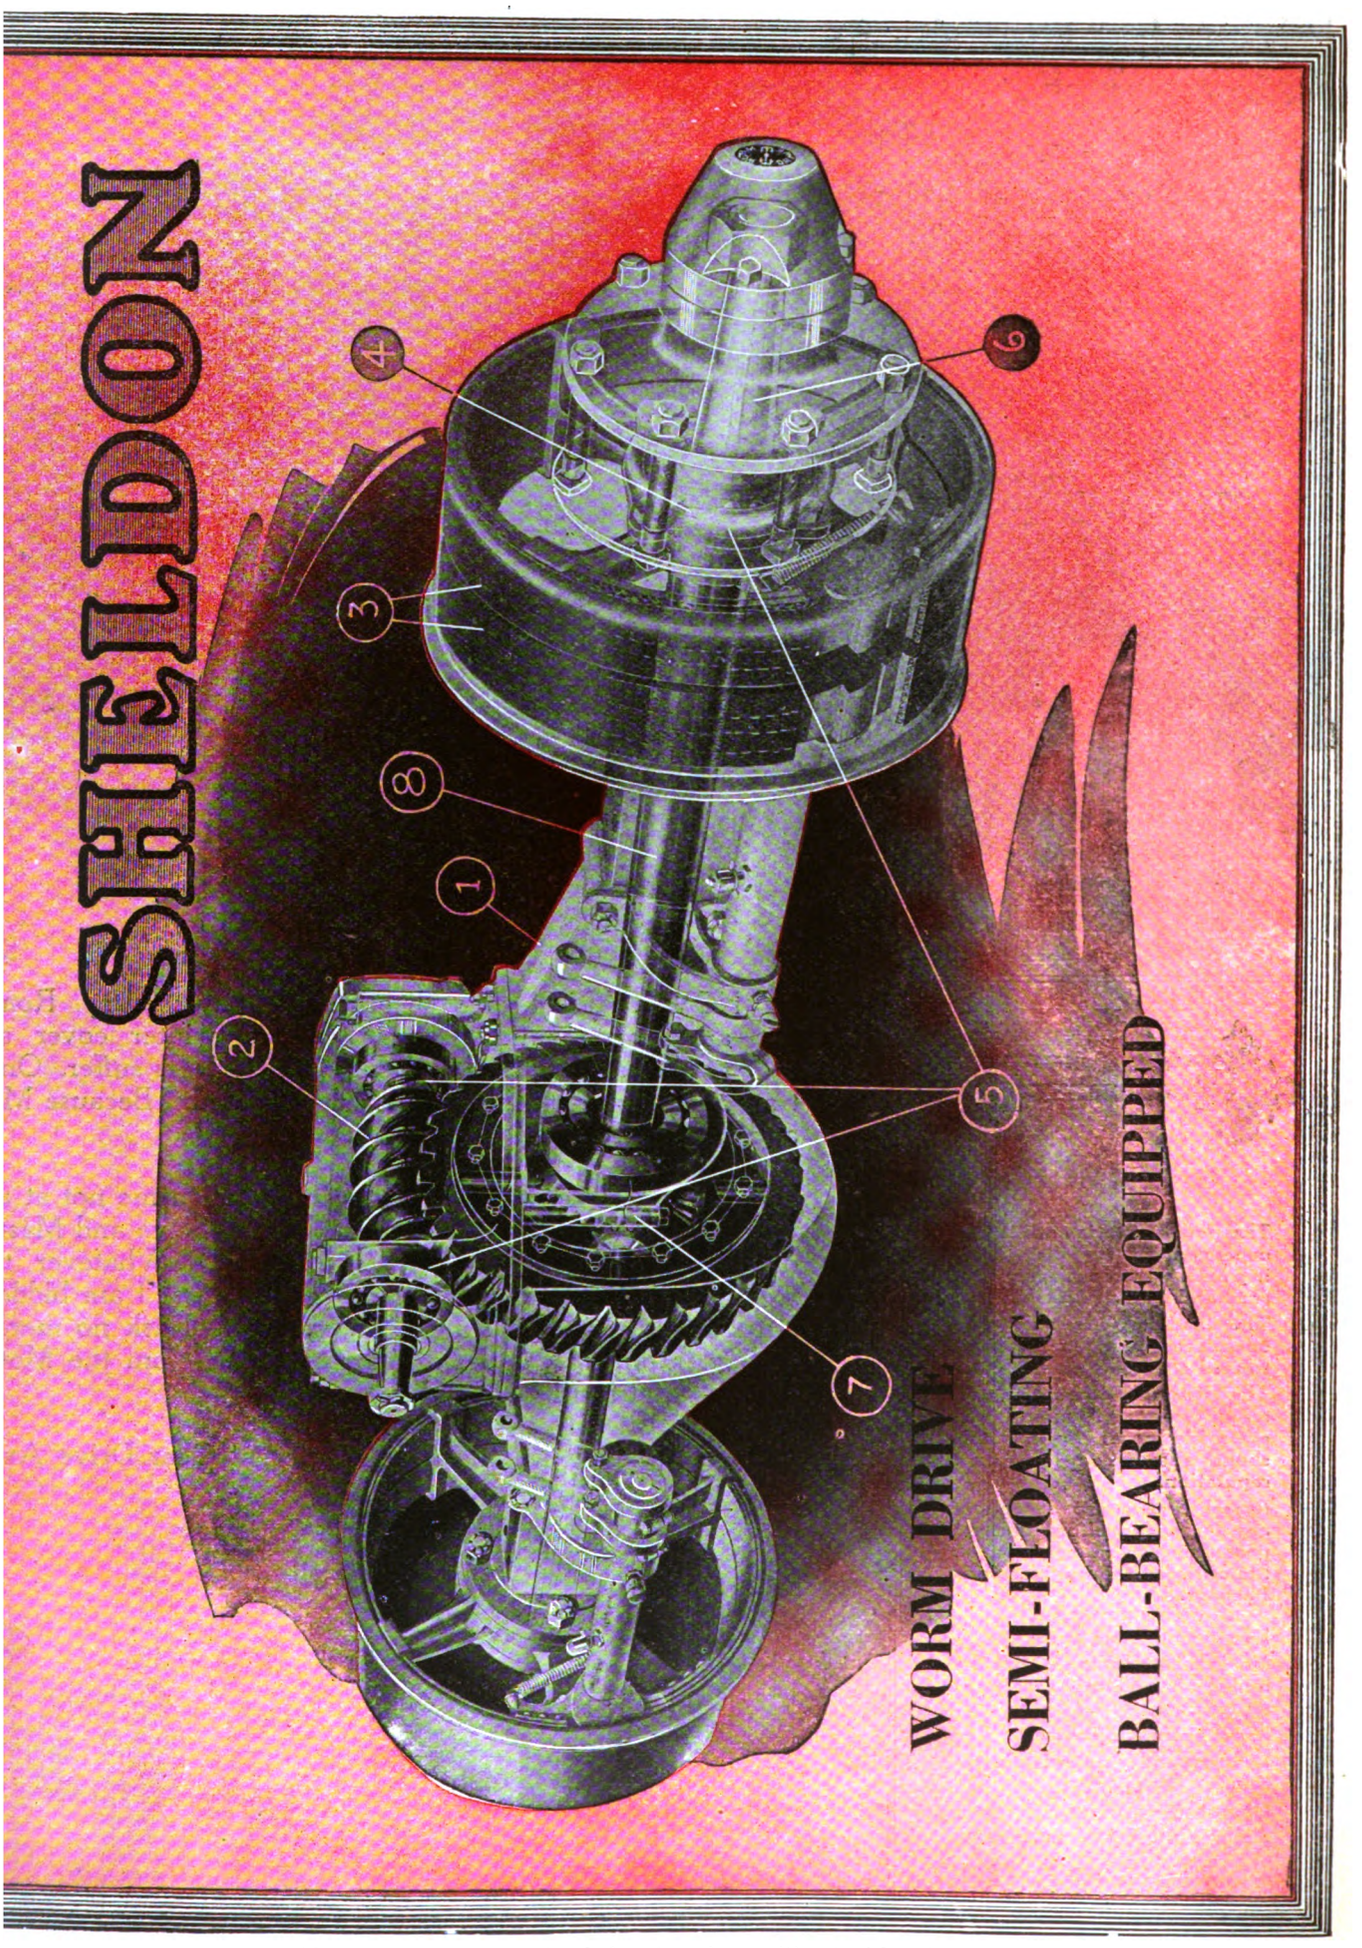
Less dependent upon lubrication.

Operating cost less.

Assures more tire mileage.

—THAN OTHER TYPES

SNOW FALLS. Ice sheathes the pavements. Roads are frozen mud. The rigors of winter cover all. Horses are crippled and die—their drivers suffer. Once transportation—at Zero—faltered or ceased. Because Man and Beast are frail.



But snow, ice, zero and heavy-going concern me not at all. I am the Motor Truck. I am at once the Slave and Master of Men—though I am Man's Creation. Whatever the weather or the road, I go where and do what I am bidden. I ask no questions. I make no excuses. I ask no mercy. I obey implicitly. I perform irresistibly. I am the Motor Truck—that is all.

I am equipped with the Russel Internal Gear Drive Axle.

SHELDON

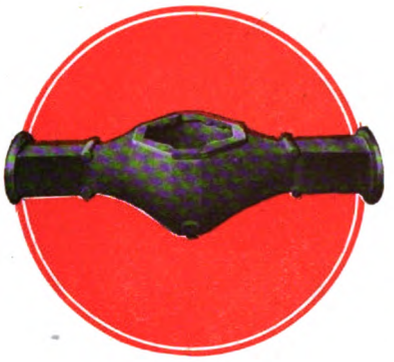
SHELDON was first in America to build worm-drive axles successfully for the trade. For more than 50 years Sheldon has led in the scientific development of heat treating fine steels.

SHELDON axle design and construction, therefore, has attained its present high standards by a natural development through the continuous striving by men of knowledge and experience to meet *actual service conditions*.

THE SHELDON Worm-Drive Axle contains no mechanical unit, embodied no principle of construction, that has not proved its superiority by years of service under varying conditions, over thousands of miles.

1. One-piece cast-steel housing, built like a bridge and just as strong. Lightest and strongest type of construction known.
2. Straight or David Brown type worm. Highest efficiency longest life, guaranteed for one year, mileage 100,000 miles and upward frequently reported.
3. Double internal brakes. Powerful, quick-acting, unfailingly sure. All working parts enclosed and protected from foreign substances. Unequalled for economy of upkeep.
4. Semi-floating wheel bearing construction. Fewer parts, lighter weight, greater strength, economy of manufacture and operation.
5. Ball-bearing mounting throughout. High efficiency, bearing adjustments eliminated.
6. Tapered hub mounting. Permits of demountable wheel, makes tire changes quick, easy, economical.
7. Oversize differential. Never wears out, built to outlast the truck.
8. Big husky drive shaft, 3½% nickel steel forging, correctly heat treated, tapered from differential to wheel bearing, gives strength where needed for every character of stress imposed upon it.

Sheldon Axles are more than correct in theory; they have been PROVED IN PRACTICE

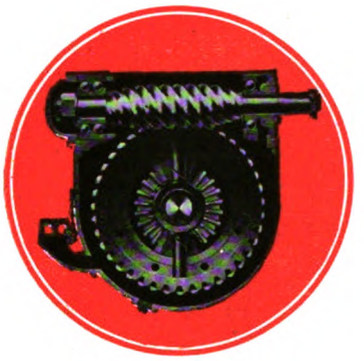


SHELDON AXLE & SPRING CO.

Makers of Axles and Springs for Heavy Duty Service for over 50 Years.

WILKES-BARRE PENNA

Digitized by Google



SHELDON AXLE & SPRING CO.,

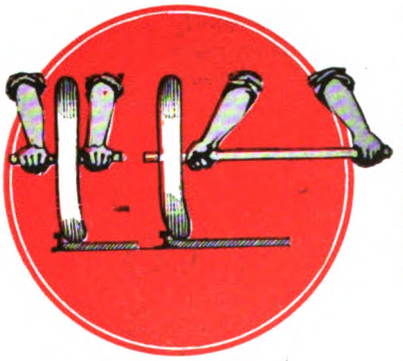
1 The Sheldon Worm-Gear Axle is encased in a *one-piece* housing. This means that instead of the various parts being cast separately and then welded together, the complete housing is cast in one mould. By virtue of this one-piece construction, there can be no loosening of parts, regardless of road or operating conditions—an extremely vital factor to consider where commercial haulage is concerned.

The one-piece axle housing furthermore protects and strengthens the working parts in a manner that cannot be duplicated in any other form of construction.

It requires from 90 to 100 tons hydraulic pressure to bend the housing double; even then it does not crack, owing to the extreme toughness of the metal used—the result of careful and expert annealing.

2 The Straight or David Brown type of worm is used in the Sheldon Axle because it has proved to be more silent and more durable, as well as the simpler of the two types of worm generally in use. Neither use nor abuse can make it noisy.

Forged from the finest steel, and heat-treated to wear-proof toughness, the worm threads are machined to microscopic limits.



The worm carrier, in which the worm is mounted, is a substantial casting, machined so accurately that later adjustment is never necessary.

The lower section of the worm wheel runs in a bath of oil in the base of the housing. This is splashed through the worm shaft bearings, maintaining a constant film of oil between the surfaces of the worm threads and the teeth of the worm gear.

3 To insure complete safety of operation, Sheldon brakes are made ultra-efficient. This is accomplished by means of double external expanding type of brake—simple in operation, self intensifying, easily adjusted, exceedingly powerful, quick-acking and unfailingly sure.

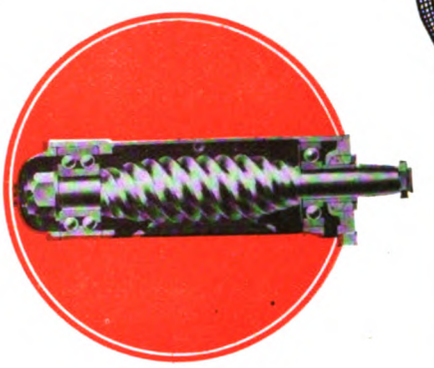
Sheldon brakes have a generous bearing surface and are doubly enclosed to thoroughly protect the bearing surfaces from dirt, grit and other foreign substances. The brakes are easily accessible for relining. When it comes to the question of adjustment, it is not necessary to touch the brakes themselves; they are tightened merely by moving back the sector to which the brake pull lever is bolted, and inserting the lever bolt in the next hole.

4 Sheldon axles are of the semi-floating wheel bearing type. Consequently Sheldon axles are more simply constructed by reason of fewer parts, lighter in weight for the same reason, yet have a greater carrying capacity than the full-floating type. This simplified construction means greater accessibility and the greater carrying capacity means greater economy of upkeep and operation.

The wheels in the Sheldon axle are mounted on an extra heavy axle shaft which bears the dead load of the truck. In the full-floating type the wheels are mounted directly on the less dependable tubular extension of the axle housing—a construction in which any slight bending, as a result of skidding or other causes, requires an expensive replacement—generally a factory repair job.

But the greatest advantage of Sheldon semi-floating construction is graphically shown in the sketch opposite. To the left (Fig. 1) is illustrated the simple leverage angle of the full-floating type against the side strains at the wheel rim, and to the right (Fig. 2) is shown the wide leverage angle of the Sheldon semi-floating construction. Obviously the latter incorporates the correct principle for resisting side strain.

SHELDON



Digitized by Google

Makers of springs and axles for heavy duty service for more than fifty years. **WILKES-BARRE, PA.**

5

It is borne out by innumerable tests, conducted under every imaginable condition, that ball bearings offer less friction and have greater load capacity than any other type of anti-friction device invented. This is particularly true under the wedging action of a thrust load of such proportions as is exerted on the worm. Furthermore, in the case of the worm, the use of the ball bearings is the only way whereby the elongation of the worm due to frictional heat can be perfectly compensated. This is accomplished by leaving the annular ball bearing placed at the front end of the worm, free to float.

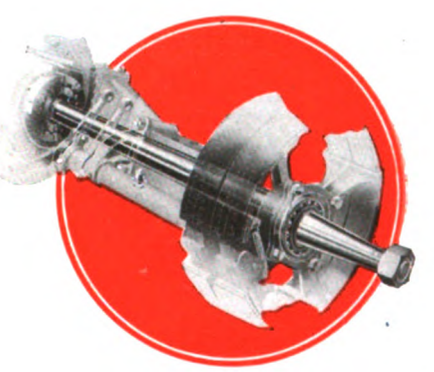
Finally, and of great importance, ball bearings do not require the adjustment which other bearings, by their nature, must receive.

6

The Sheldon wheel bearings are enclosed in the main axle housing. They are thus protected against grit and other foreign matter when the wheel is demounted At the same time the bearings are easily accessible, it being necessary only to remove the wheel and then the bearing retainer in order to get to them.

The shape of the hub itself gives greater strength where greater strength is needed, and furthermore allows the easy demounting of the wheels, thus making a change of tires quick, easy and economical.

7



As far as we can learn, not a single Sheldon differential has ever worn out. Notice how the gear teeth, instead of being concave in design are broad and thick at their base, this providing ample protection against gear stripping and quick wear. Each bevel gear is supported *on both sides* by an intended hub inserted into a bearing ring in the spider. This insures absolute alignment and eradicates all possibility of faulty performance. Strength is further continued with efficiency in the hexagonal broaching of the differential gear to receive the axle shaft. A square insertion would permit quick wear, a splined insertion would weaken the metal. Sheldon design avoids both weaknesses.

8

The big, husky Sheldon drive shaft is a forging 3½% nickel steel; accurately proportioned, expertly heat treated, and ground to size.

The distribution of strain along this length dictates a taper from the differential to the wheel bearings—thus a uniform strain is secured throughout and ample strength is provided where needed.

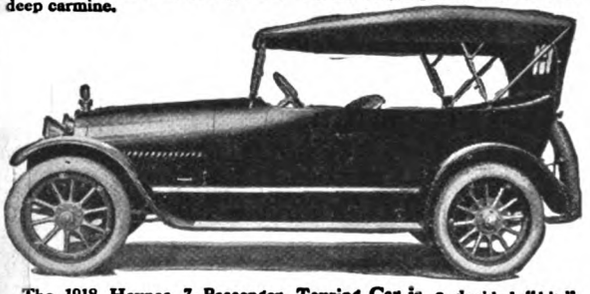
The 25th Successful Year of HAYNES



"America's First Car"

The 1918 Haynes Ultra-Smart Town Car. Seats seven—five inside and two in the driver's compartment. The plate glass windows may be lowered by means of convenient lifts. Perfection heater. All the luxuries. Colors: Royal green, beige brown, deep carmine, Haynes blue.

The 1918 Haynes "Light Six" 5-passenger Touring Car. $1725. Note the broad-chested, high-arched hood, the straight lines, the curve to the fenders, the double cowl, the rakishly tilted windshield. Plenty of room and "then some" for five. Deep springs in the comfortably shaped cushions increase the riding-ease. Colors: Royal green, beige brown, deep carmine.

The 1918 Haynes 7-Passenger Touring Car is a decided "hit." The center cowl panel is of beautiful American walnut. Auxiliary seats fold into it. A convenient package compartment is at the center. The upholstery is deeply cushioned and French pleated. All the "little details" are correct. Colors: Deep carmine, royal green, beige brown.

"The Prettiest Roadster in America" is the Haynes 1918 Roadster for Four—The "FOURDORE." The lines speak for themselves. Built upon the 127-inch 7-passenger chassis, ample leg-room is provided both in rear and front for "six-footers." Carrying compartment in rear. *Four doors.* A stunner! Colors: Beige brown, deep carmine, royal green.

DEALERS:

THE mature Haynes motor, America's Greatest Light Six Engine, now in its 42nd month of success, virtually without change, is continued. Over a quarter billion miles of driving by more than 20,000 average owners, have proved it the best "six" in its class for performance, durability and *low upkeep.*

The chassis now has six-inch side members. 39 x 2¼ inch front springs and 58 x 2¼ inch rear springs assure maximum easy-riding by reason of their generous size and resiliency.

There are six beautiful new bodies in a range of colors for 1918. Note the high, broad-chested hoods, tilting windshields, double cowls, etc.

Haynes, "America's Greatest Light Twelve," winner of fast racing events this past season, is also offered in five new bodies of striking appearance. Wire wheels and cord tires are regular equipment.

Haynes national advertising—pages both in colors and black and white—in leading weeklies and monthlies, and dominating space in a long list of the best farm papers, pages in motoring publications, etc., is exerting a greater selling force in behalf of the dealer than ever before in Haynes annals.

Haynes co-operation with the dealer in his local publicity is likewise intelligent, willing and liberal.

A beautiful automobile catalog portrays these latest Haynes offerings in full. Proudly will these be handed to prospects by Haynes dealers this year.

Send for a copy—and for the full "*Haynes 1918 Proposition to Live Dealers.*"

Dependable Spark Plugs

The Conservation of Retail Profits in Spark Plugs

Because the Retailer's business is on a smaller scale than the Jobber's he is more apt to overlook those factors which dissipate his profits.

In an unguarded moment the busy Retailer may thoughtlessly accumulate profitless stock.

Stock that moves slowly or stalls in the Retailer's shop dissipates the Retailer's profit just as it does the Jobber's.

The normal sale of Champion-Toledo Dependable Spark Plugs will yield the Retailer more spark-plug profit than he can possibly exact from even the forced sale of other spark plugs.

Likewise, and for the same reason, a little selling effort behind Champions yields bigger results than a like amount of effort behind any other plug.

And that reason?

It is the normal demand of an experienced and appreciative buying public.

That normal public demand for Champions is greater by far than for all other spark plugs combined.

And it is a dependable demand because it is based on the superior efficiency and durability of Champions demonstrated and proven by the motor car owner's experience.

If you as a Retailer doubt the greater volume of Champion business, note the prominence and space given to Champions in all Jobbers' catalogues and ask yourself why.

Champion Spark Plug Co., Toledo, Ohio

Champion Toledo

Dependable Spark Plugs

How Jobbers Conserve Their Spark Plug Profits

Two things are apt to dissipate the jobber's profit,

—slow selling goods that tie up capital until carrying cost eats into profit,

—goods that move not at all until profit is sacrificed by a cut in price or in costly special selling effort.

Jobbing profits are in those articles that sell steadily in large volume.

From such articles the jobber may by skillful buying extract the last penny of possible profit.

One of the best examples of profitable jobbing merchandise is the Champion-Toledo Dependable Spark Plug.

Champions have a sales impetus which makes them "flow" through the jobbing channels in a big steady stream.

They pause in his stock room barely long enough to be checked in.

And in paying quickly they pay big.

So those jobbers who carefully conserve their profits, stock Champions liberally so as never to miss profits through inability to make prompt and full delivery.

And they restock fully and promptly to keep the stream flowing in largest possible volume—yielding its steady toll of maximum profit in ever increasing amounts.

CHAMPION One Piece "Heavy Stone"

G15, ⅞—18
Price $1.25
Recommended for use in:
Murray, Owen, Cuto, Willys-Knight, Moline-Knight, Stearns-Knight, Willys-Sls
And all Knight motors.

CHAMPION "Heavy Duty" for DODGE CARS

J13, ¾—18
J63, Metric
Price $1.00
Recommended for use in:
Apperson, Briscoe, Crow-Elkhart, Elmar, Franklin, Hupmobile, Jackson, King, McFarlan, Monroe

CHAMPION "Heavy Duty" for PACKARD CARS

JA13, ¾—18
Price $1.00
Recommended for use in:
Packard, Pierce Arrow, Peerless, Mercer, Cadillac, Chalmers, Chandler, Marmon, Cole, Dorris, Haynes, Oldsmobile, Hudson, Kissel-Kar, Velie

CHAMPION "Aeroplane"

3 16 63, Metric
Price $1.25
Specially constructed for all types of aeroplanes and motorcycles.
Not affected by heat or oil conditions.

CHAMPION Two Piece "Heavy Stone"

B13, ½ Inch
B13, ¾—18
B63, Metric
Price $1.25
Recommended for use in:
Austin, Fiat, Case, Marmon, Stutz, Locomobile, White
And heavy service trucks and tractors.

CHAMPION "Sparks-in-Water" MARINE

DC13, ¾—18
DC13, ½ Inch
Price $1.25
Ideal plug for motorboat use. Moisture, fog and rain on the outside of this plug does not interfere with its operation.

CHAMPION "Long" for "REO" CARS

A23, Long ½ Inch
A24, Extra Long ½ Inch
Price $1.00
Recommended for the Reo car and other automobiles and engines requiring a long type of plug.
Extra long extension for the Mota car.

CHAMPION "Priming"

H13, ½ Inch
H14, ⅝—18
H63, Metric
Price $1.25
Will start any motor on the first quarter turn.
Brings gasoline right to the sparking point. A good winter seller.

Champion Spark Plugs

All Champion Spark Plugs are guaranteed to give absolute satisfaction to the user, or full repairs or replacement will be made.

CHAMPION "O" for OVERLAND CARS

J13 "O", ½ Inch
Price $1.50
The Overland factory equipment plug. Especially recommended to meet the requirements of the Overland motor. Also recommended for tractors, farm, stationary, marine engines and all automobiles where a standard ½ inch plug is used.

CHAMPION "X"

Adopted by the Ford Motor Co. as standard equipment on Ford cars since 1911.

A15, ½ Inch
Price $0.75
The following is quoted from the instruction book in each Ford car:
"There is nothing to be gained by experimenting with different makes of plugs. The Ford engines are equipped when they leave the factory are best adapted to the requirements of our motor.

CHAMPION "Maxwell" for MAXWELL CARS

A44, ⅞—18
Price $1.00
The Maxwell factory equipment plug.
Has the well-known patented Copper Asbestos gasket construction which does not allow any metal to touch the shoulders of the porcelain.

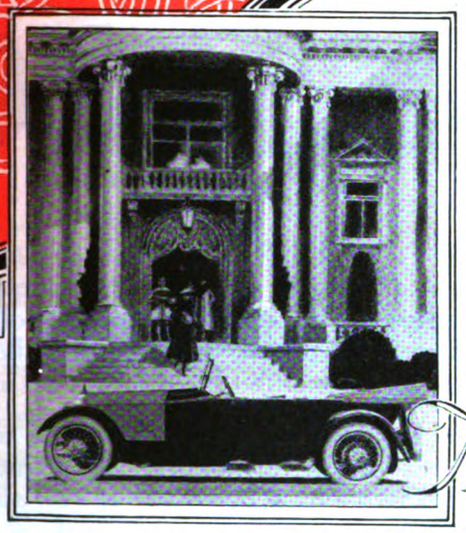
CHAMPION "Studebaker" for STUDEBAKER CARS

AA13, ½ Inch
A43, ⅝—18
Price $1.00
Recommended for the in:
Allen, Auburn, Dort, Elgin, Grant, Jordan, Liberty, Mitchell, Paige-Detroit, Saxon, Spaulding, Stewart.
And tractors, farm, stationary and marine engines where a standard ⅝—18 plug is used.

CHAMPION PORCELAINS

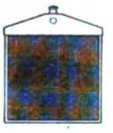
A 165 "X" Price $0.40

B 102 Heavy Stone Price $0.60



A 103 Conical Price $0.45

CHAMPION "Buick" for BUICK AND CHEVROLET CARS



A53, Long, ⅞—18
Price $1.00
Has long shell, conical porcelain. The long shell allows the spark to ignite within the cylinder instead of in a pocket, as occurs when the ordinary type of plug is used.

1918 Jobber's Catalogue Pages

Digitized by Google

To the svelte, smart lines of Roamer European body design have been added new aristocracies. To high mechanical merit have been added new qualities of time and distance dominance. Again this year, as heretofore, Roamer leadership is acknowledged.

The ROAMER

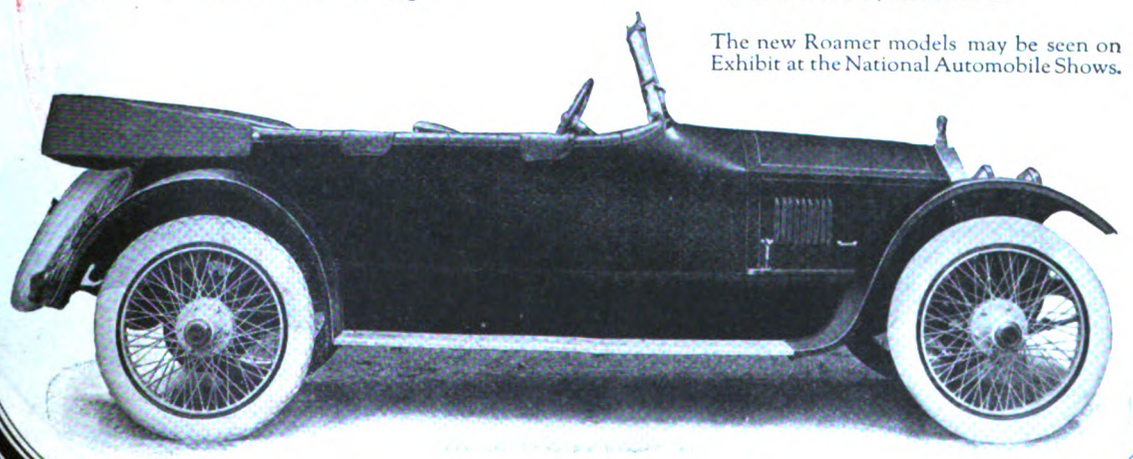
America's Smartest Car

An unimagined speed radius and control flexibility at a minimum usage of fuel and oil is now available in the new Roamer Six, with its special Roamer Continental motor.

To the pride of possessing this masterly motor car is added the new pride that will come from its performance under all sorts of driving conditions.

Besides the four-passenger Continental-motored Six, the new Roamer models also include a new six-passenger triumph of body-building on the same sturdy Roamer chassis.

As before, each Roamer is supplied, at no increase in price, in the purchaser's option of body finish, color, upholstery materials and top.



Each Roamer is equipped at no extra cost with a sylphon thermostat, Boyce motometer, Bosch magneto, wire wheels and Goodyear cord tires.

The ROAMER with Duesenberg Motors

The present needs of the nation have limited our expected production of Roamer models equipped with Duesenberg motors. A few orders for deliveries of four-cylinder Duesenberg-motored Roamers in four-passenger sport type models will be accepted. These are identical with the Roamers in which Eddie Hearne and Pete Henderson recently made their record-breaking track performances at Chicago, Uniontown and Los Angeles. Available also, a limited quantity of the standard 6-90 Roamers in sport car and seven-passenger types.

Barley Motor Car Company
KALAMAZOO, MICHIGAN

The new Roamer models may be seen on Exhibit at the National Automobile Shows.

Roamer 4-passenger Continental-motored four

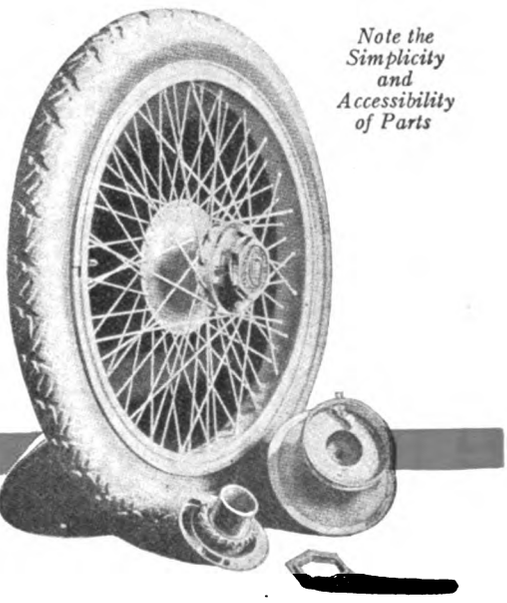
Three Exclusive of PASCO

1. **THE PASCO WIRE WHEEL** has a PATENTED FOUR series method of Rim Punching and Spoke Lacing which makes it stronger than any other wire wheel and 60% stronger than wooden wheels. All spokes cross four others in both the front and rear rows, forming a strong double web in the spoke lacing of the wheel hub and rims. Previous methods allow but two or three crossed spokes.

2. THE PASCO HUB CAP is made of a strong, indestructible metal that stands up in crowded traffic collisions, where aluminum, brass and other soft metal compositions will strain or break.



Unusual care has been taken to make it sturdy, massive looking, yet attractive.

Patented Features
WIRE WHEELS

3. THE PASCO PATENTED SAFETY LOCKING DEVICE locks the hub cap and wheel on to the threads of the inner fixed hub and axle with a vise-like grip. The device absolutely cannot work loose and allow the wheel to come off from a moving car. It is positive insurance against accident from such a cause. The only possible way to remove a hub cap is to loosen the locking device and use a Pasco wrench.

Note the Simplicity and Accessibility of Parts

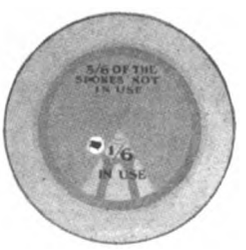
Dealers and Users

Pasco Wire Wheels Are Tire Savers. As they revolve the angle of the steel wire spoke lacing produces much the same effect as a radiator fan. A continuous current of cool air encircles the tire and dispels the heat, which is its worst enemy. In actual practice the saving in tires amounts to from 25% to 50%—more than enough in a year to repay the extra cost of the Pasco Wheels.

Pasco Wire Wheels Are Economical. Their very lightness allows a quicker car "get-away" and a quicker stop—with less power —which means a distinct saving in fuel consumption.

Their shock absorbing construction reduces road strains to a minimum and saves repair bills.

The speed and ease with which they can be replaced on the road means a further saving of time and money—it takes three minutes for the average car owner to change wheels and he doesn't need to get dirty doing it either.



Pasco Wire Wheels give an air of distinctiveness and beauty to the car, an impression of style and speed and class which will appeal to all motorists.

Write today for particulars and prices.

AT THE SHOW

★Hartford EQUIPMENT

★ Hartford Shock Absorber

See it practically demonstrated. Learn how it *constantly* controls every move on an automobile spring. Note the smoothness with which the spring contracts and recoils. No harshness, abruptness. Then the realization will come of its necessity to broaden your range of riding because it really *Makes Every Road a Boulevard.*

★ Hartford Bump Absorber

The car guard which protects in fullest measure. Practically break-proof, positively bump-absorbing. Flexes when striking, taking the sting out of the blow, saving not foreparts alone but all the car from strain and its passengers from jar. See it at the show.

★ HARTFORD AUTO JACK

All that jack de luxe should be—*Strong* with the strength of solid-steel working mechanism and tough malleable-iron case; *Easy-working*—it lifts a heavy car with a wrist movement; *Handsome*—beautifully finished in black and gold; *Convenient*—Easily slipped under an axle and operated without stretching or straining. Long handle, short stroke; firm, solid base. Try it at the show.

LAMINUM

OF COURSE!

IN ENGLAND—AND FRANCE

Laminated Shims will be used in the

English Military Motor Transport Service

and will be stocked by the M. M. T. Depots of the British Army. They have also been introduced to the Air Board and will be used by all transport vehicles in the air service.

IN AMERICA

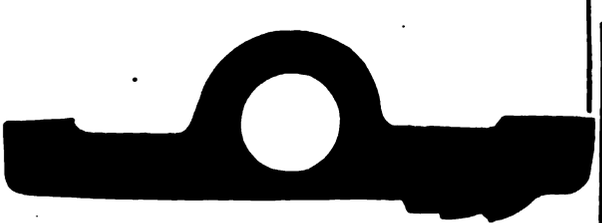
Specifications of the S. A. E. are as follows:

"89. The main and connecting rod bearings shall be provided with laminated metallic Shims, made up of sheets of equal thickness. The shim sheets shall be not more than 0.002 in. thick."

Extract from Standard Specifications for Motor Trucks, classes A & B, prepared by Motor Transport Board of War Dept. on recommendation of S. A. E.

THE REASONS

The reasons for these official endorsements of laminated shims are that they have all the advantages of solid shims—plus the advantages of loose-leaf shims. They allow quick, accurate adjustments, and present a clean, smooth surface *always*.



If you do not know Laminum, send for a sample

Red Head

TRADE MARK REG. U.S. PAT. OFF.

Vitristone PLUG

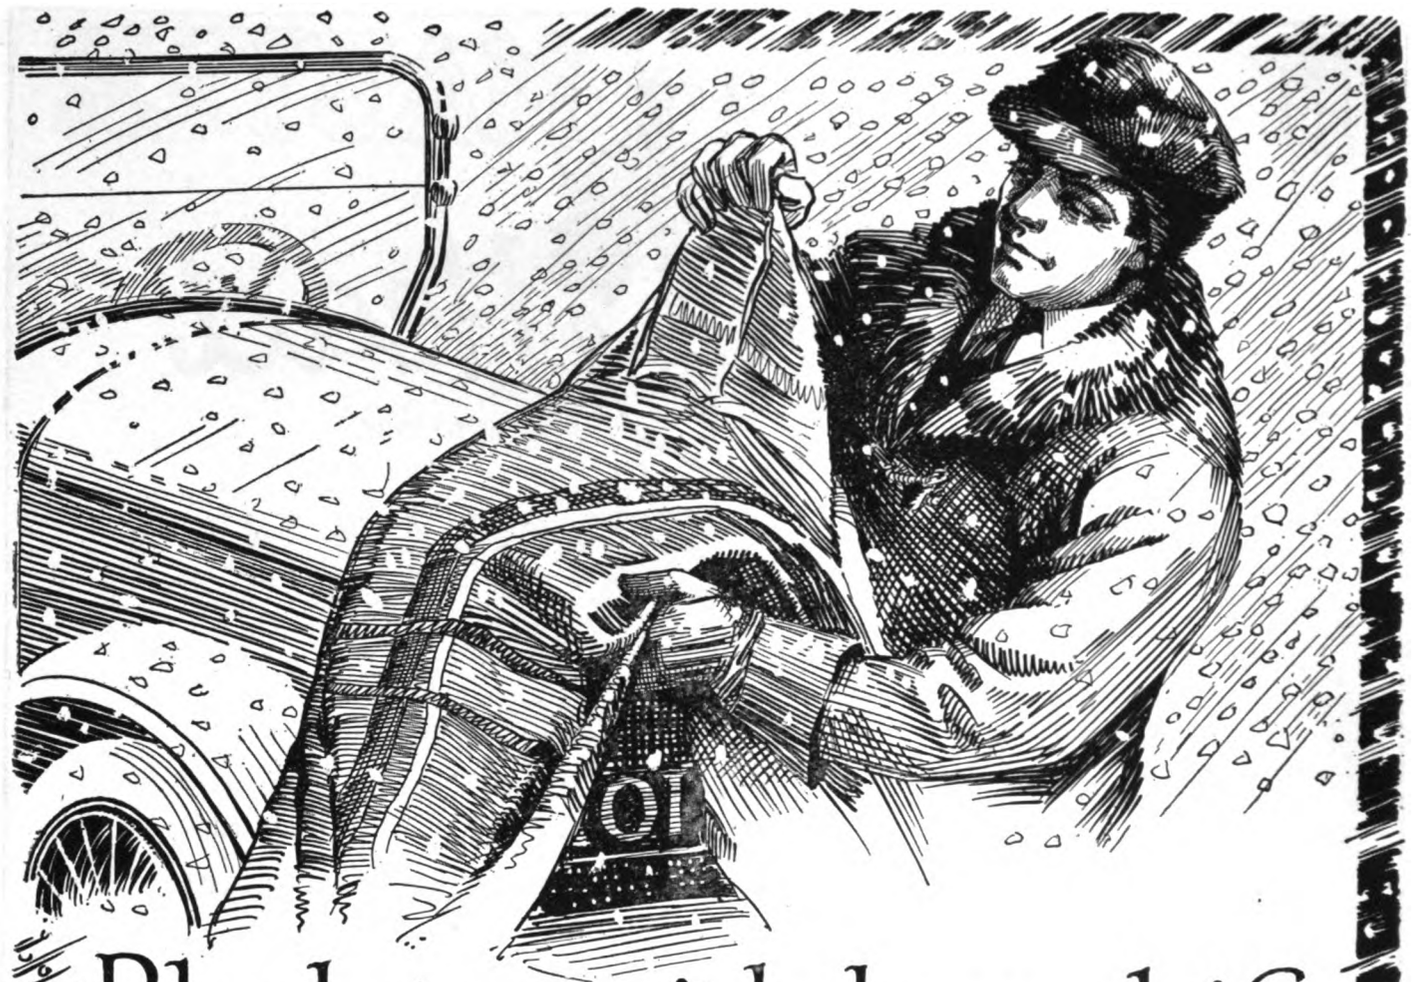
Vitristone is making good.

Vitristone is standing up in motors that are terrors to porcelain plugs.

Vitristone makes porcelain plugs obsolete.

Vitristone is not a substitute—it is the successor of porcelain as a spark plug insulator.

Vitristone is to porcelain what a stone crock is to a China cup.



You don't have to pay more for Red Head Vitristone Plugs, but you must buy Red Heads to get Vitristone—it is made for and used exclusively in Red Heads.

When you buy Red Heads, insist on plugs with the red-enameled bushing—as shown in the cut. Only then are you sure of Vitristone.

Blankets won't help much if—

the oil you are using does not flow freely at Zero.

SUPREME AUTO OIL flows freely at Zero.

STARTS WITH THE ENGINE

THIS is most important during the Winter months. You should know whether the oil you are using "flows freely at Zero." All oils do not possess this feature—notably the paraffine-base oils, which thicken up under cold and often cause great damage to the motor.

The safe way is to ask for SUPREME AUTO OIL—it "Flows freely at Zero" and leaves less carbon, owing to the fact that it is a Southern Asphalt-base oil containing no paraffine to gum, stick or thicken.

Ask him about his brakes

The safety of his car depends on the brakes

When your customer stops for "gas" or comes in for supplies, ask him about his brake lining. Because it is hidden out of sight most car owners do not give it the attention it deserves.

The safety of the car and everyone in it depends on the efficiency of the brakes. Call this to his attention and you are sure to increase your volume of relining business.

When you reline his brakes put on brake lining that will make him a satisfied customer. Thermoid Brake Lining makes satisfied customers for three reasons:

More material, greater service

There is over 40% more material and 60% more labor used in the manufacture of Thermoid Brake Lining than in any woven brake lining. This abundance of material and labor means longest wear, greatest safety and lowest final cost.

Grapnalized

Thermoid Brake Lining is Grapnalized, an exclusive process which resists oil, gasoline and moisture. Under ordinary conditions of service Thermoid is impervious to the action of water, gasoline or oil. Moisture of any kind causes ordinary brake lining to swell, making it grab or slip.

Ideal surface, uniform wear

Every inch of Thermoid is compressed under 2000 lbs. of hydraulic pressure.

Because of this process Thermoid is uniformly hard all the way through. It cannot squeeze down after it is applied. There are no soft spots to wear out quickly and cause the brakes to grab or slip. That is why it is 100% brake lining. Thermoid Brake Lining will wear better and last longer because it is hydraulically compressed. It is brake lining clear through.

Make this comparison

Actual comparison between woven brake lining and Thermoid Brake Lining quickly shows why Thermoid is the safe brake lining. We will be glad to send sample of Thermoid. Simply put your name on a postal and send it in.

Brake Inspection Movement

Within the past few weeks a movement has been started to promote the regular inspection of brake equipment by every motorist. This movement is endorsed by leading individuals and organizations in the automobile industry throughout the country.

The first object of the movement is to have all brakes inspected before the touring season opens. This will decrease the accidents due to faulty or improperly adjusted brakes. This movement merits your support because it will increase your brake lining business.

A larger campaign than ever before will run throughout the year to convince motorists of the superiority of Thermoid Brake Lining. When they ask for Thermoid be prepared. Your jobber will supply you.

Our Guarantee: Thermoid will make good, or we will

For the past six years Multibestos has been the first choice of engineers and manufacturers who select their brake lining on the basis of competitive tests.

MULTIBESTOS
BRAKE & CLUTCH LININGS

This well-known product needs no introduction, as the service it has given since being placed on the market has proved it to be without a peer in its field. The adoption of Multibestos as standard equipment on such cars as the Packard, Pierce-Arrow and Locomobile is proof of its superior quality.

Digitized by Google

Multibestos is manufactured complete in our own factory. This is a fact worth considering, for it places upon us the full responsibility for quality. Not only do we weave Multibestos—we spin every strand of the yarn that goes into its make-up. Every process is under the direction and close inspection of our own experts.

By thus controlling the entire course of production, we are able to guarantee the quality of Multibestos and offer to each user the most complete satisfaction.

Back of every foot of Multibestos stands the largest and most complete factory devoted to the manufacture of brake and clutch linings.

Climbing

¶ The mountains show up the true colors of your car. Its 83 horsepower motor is equal to the sternest climb. You hit the grade at 30 miles per hour. And behold, the little needle is still at 30 when you reach the top. Or throttle down and see what she'll do. Watch your speedometer—10 miles an hour, 5, 3, 1½. It hardly seems possible—and your gear is still in "high". Yet not a sign of laboring. Now give her gas. Forget your gears. Gathering speed like a bird or aeroplane, you complete your climb in a whirl of 40—or even 50-mile-an-hour strainless motion. ¶ Distributors and dealers in territory still open are invited to call on any of our representatives for a ride in this truly wonderful car.

Miller Carburetor

For a Faster, More Powerful, More Economical Car in 1918

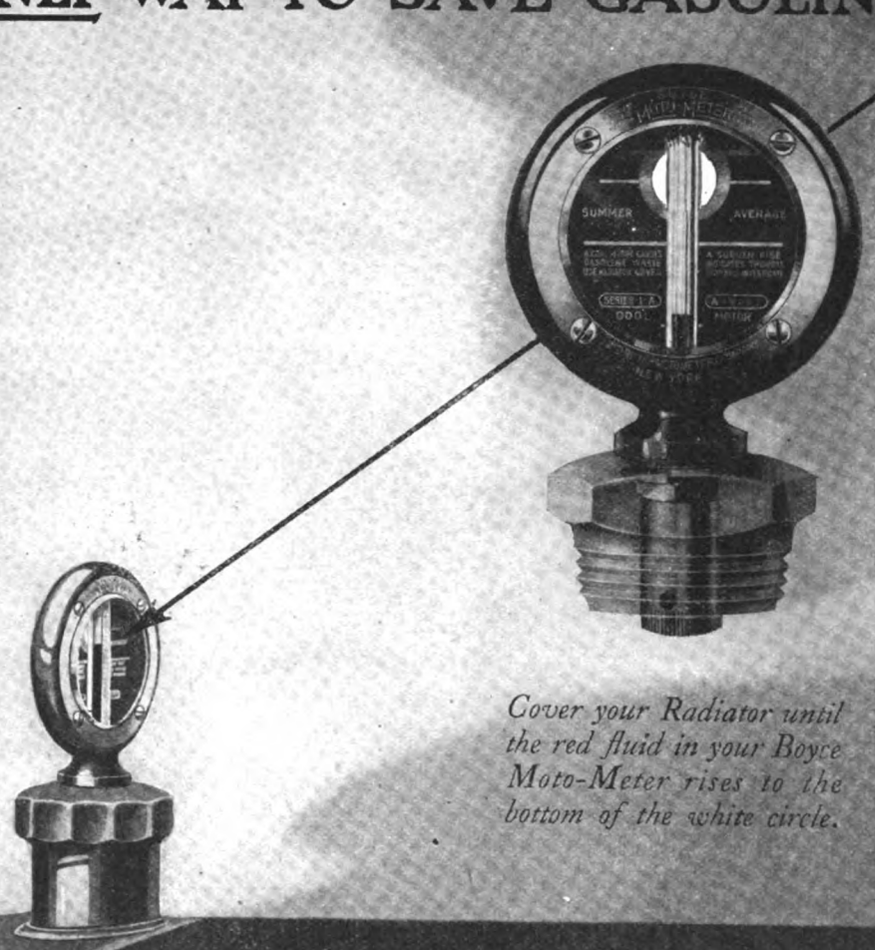
THIS year it will mean more than ever to you and your car—a speedy, high-power, big-economy Miller Carburetor.

It will help put your motoring on an efficiency basis—a patriotic basis.

It will help you get a whole lot more out of your motor by thoroughly vaporizing the present low grade fuel.

Miller is acknowledged WORLD'S CHAMPION on speedway and race course. And in everyday service on passenger car, truck, tractor or aeroplane, its performance is every bit as remarkable.

Positive, automatic action and unequalled simplicity are the reasons.



Let us show you how to make your car a **better** car. Write us.

THE ONLY WAY TO SAVE GASOLINE!

Cover your Radiator until the red fluid in your Boyce Moto-Meter rises to the bottom of the white circle.

ENGINEERS have been telling us for years that the only way to save gasoline is to operate the motor at a high temperature.

If this is not done 30 to 40% of your gasoline goes out the exhaust pipe unburned and wasted.

Don't blame the manufacturer of your car for poor gasoline mileage. His duty was at an end when he supplied you with a Boyce Moto-Meter.

Cover your radiator until your Boyce Moto-Meter reads Summer Average. Then and then only will you start saving gasoline—simple isn't it?

The Motor Dictograph

Starts 1918 with a Record Unequalled in the History of the Automobile Industry

FIRST displayed in the 1917 Salon and Shows—during the year it has been adopted by the great leaders in the motor world. It is standard equipment in Packard, Cadillac, Hudson, Winton, Willys, Jordan, Cunningham, Murray, Roamer, Owen-Magnetic, McFarland, Cole, Chalmers, Liberty, Pierce Arrow and others. Holbrook Company and other famous body builders use it exclusively in the finest custom work.

The Motor Dictograph is the *Automobile Telephone Par Excellence.* Nothing else can take its place—nothing else can be near as good.

The Motor Dictograph is fully protected by patents. All infringements will be rigorously prosecuted.

For 1918 we will bring out our CABINET TYPE MOTOR DICTOGRAPH for installation in closed cars now equipped with obsolete type telephones. Manufacturers, engineers, designers, dealers and service stations are invited to correspond.

Our Exhibit in the 1918 Shows will be in the cars of OUR CUSTOMERS

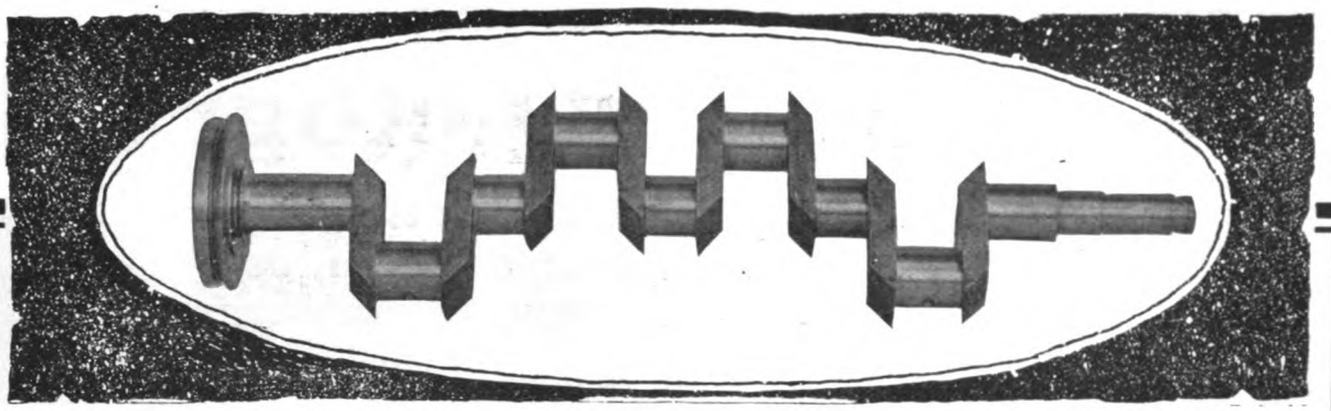
General Acoustic Company

CHAS. H. LEHMAN, Vice-President and General Manager

The Dictograph System

220 West 42nd Street New York

Branches in all principal cities throughout the world



SEND for circulars describing the famous Dictograph system of Inter-Communication, the Aviaphone, the Navalphone, the Acousticon for the Deaf—all Dictograph products.

Our new Aviaphone revolutionizes the system of communicating between the pilot and observer in an Airplane—ready early in 1918.

Executives—Attention

If you have an inter-communicating problem of any kind, the Dictograph will solve it as it has solved similar problems for the world's greatest executives. Our new booklet, "An Essay on Efficiency," will be sent free to any executive who mentions Automotive Industries in writing for it.

Crankshaft Machining

There's a mighty desirable feeling of security—a satisfying sense of safety—in the consciousness that behind your crankshaft machining there are over twenty profitable years of experience. Isn't it *something* to have applied to your work the supreme skill and thorough knowledge which have sprung from these long years of specializing?

MOLTRUP

But experience is not the sole reason for MOLTRUP leadership. Untiring vigilance over every detail—extreme care in every operation—an equipment unsurpassed in value and completeness—*these* are the factors that have enabled us to so successfully capitalize that experience.

These things mean *certainty*. They mean the kind of workmanship that quality finishing demands—the *only* kind that you can afford to employ, if you would avoid those fatal inaccuracies that the slightest oversight, or the smallest defect in tool or machinery, would render inevitable.

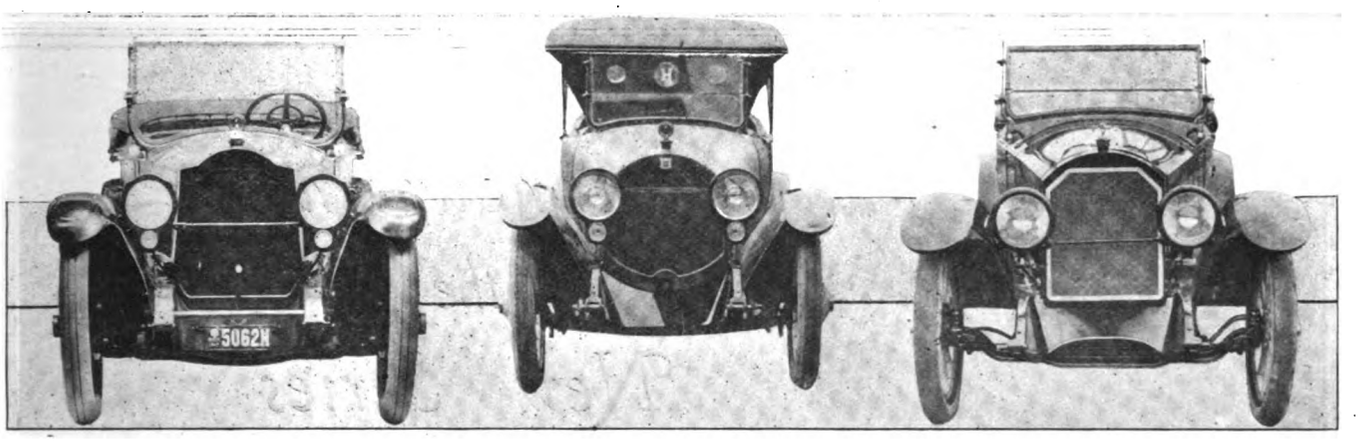
A Newer and Bigger Plant

Not long ago our plant had to be enlarged to take care of the rapidly increasing contract work we were receiving. Naturally new lathes, grinders and other equipment were installed: and now throughout our entire plant will be found the most up-to-date crankshaft machining devices in the country.

Work Done Expertly and Promptly

This greater capacity places us in a better position than ever to handle your work with gratifying promptness.

And our new equipment, backed by all that MOLTRUP stands for in expertness and quality, insures positive accuracy of alignment and balance.



Can you safely accept *less* than MOLTRUP gives? Can you possibly get *more* in any other plant? Think how all-important it is to be sure of absolute dependability—the *vital necessity* of correct machining—

And then send us your blueprints and let us submit quotations.

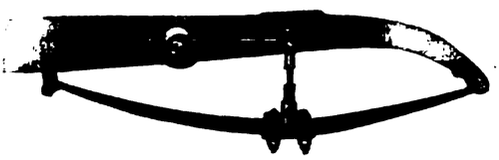
"It Is Well Known At The Front

that some ambulances can travel over rough roads faster than others, not on account of their higher power, but entirely because of their better riding qualities."



"The easiest riding ambulance of which the writer has had any experience was * * fitted with Houdaille Shock Absorbers."

(Extract from article by Mr. W. F. Bradley on the Army Ambulance Service)

The Houdaille Hydraulic Suspension (or Shock Absorber) is well known not only "at the front" but throughout Europe, where before the war it was standard equipment on 14 makes of Automobiles. It is built on the principle of the hydraulic recoil checks which have so thoroughly proved their efficiency on the French "Seventy-Fives."

HOUDAILLE

(PRONOUNCED HOO-DIE)

HYDRAULIC SUSPENSION

The simplicity of its attachment is illustrated above.

Not the slightest change is required in the body or chassis of any car.

No matter how great a resistance the Houdaille is adjusted to exert in one direction (and this adjustment is made exactly to fit your necessities by one twist of a screw driver) in the other direction it will always move with ease, so that the wheels easily drop into hole or rut without taking the car body with them.

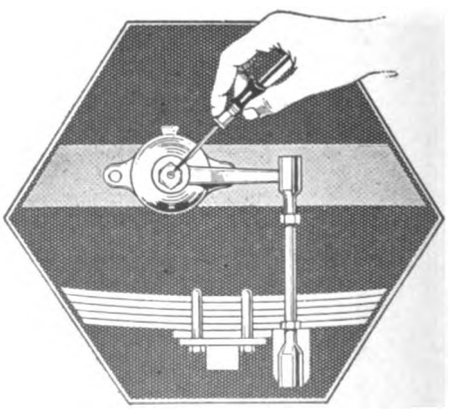
This is a very important point in the smooth, easy running of a motor car.

Prices (including installation):

Half set, two instruments.....$50.00
Full set, four instruments.....100.00

The Houdaille Shock Absorber Co., Inc.

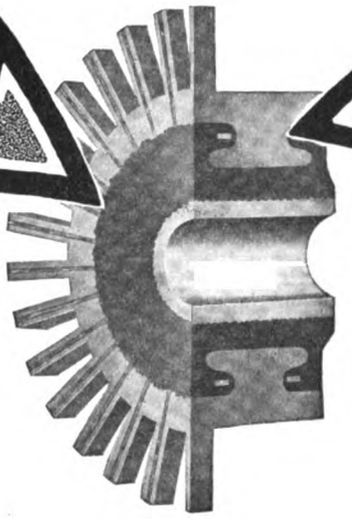
1737 Broadway, New York



PHILADELPHIA:
Auto Equipment & Service Co.
1435 Vine Street

CHICAGO:
The Arthur Jones Electric Co.
55 East 28th Street

This Shock Absorber has



ONLY ONE ADJUSTMENT

As shown in the illustration below, a slight turn of the screw fits the resistance of the Houdaille to fit the weight and spring equipment of any car.

It has only one moving part, and contains no springs. All the strain comes on the oil (Castor Oil or Glycerine) in the interior, which is forced though numerous by-passes by a rotary paddle.

Digitized by Google

SAFER AT HIGH SPEEDS— AND THE COST IS LESS

Whether you are a manufacturer of small motors, or a user, the fact that

BAKELITE
MOULDED COMMUTATORS

are safer at high speed and cost less should interest you.

Moulding the commutator segments in Bakelite means an oil-tight, water-tight, dust-proof commutator which will not work loose at high speeds because Bakelite is mechanically strong and grows harder under heat instead of softening.

When a commutator of considerable diameter is to run at high rotative speed, steel reinforcing rings may be moulded in at either end inside the sector lugs. These rings reinforce the commutator against centrifugal strain. Commutators of small diameter, such as used for small motors and fans, may not need these reinforcing rings.

Many styles of commutator are made at less cost when moulded in Bakelite for Bakelite saves the cost of mica V-rings and eliminates expensive and unsatisfactory assembling.

Saves Ford Rear End

Rear end trouble! That's a big bugaboo with Ford owners. One of the chief contributing causes is inefficient transmission lining. It gets hard and polished —then grabs and slips—and *then* there's *trouble to pay*. The Ford comes to a stop amid heavy vibration and noisy chattering. The back end vigorously jumps up and down. The *direct shock* of this vibration is communicated through the drive shaft and gearing to the rear axle. No mechanism can stand such strain indefinitely. Rear end trouble is the *natural result*. Cork Insert Transmission Linings stop the grab and slip—eliminate the chatter and permit velvety smooth transmission action. They *save* the Ford rear end—prolong greatly the life and efficiency of the car. This alone would make the use of these linings economical and advisable. In addition they outwear two to three sets of ordinary linings.

A Non-Slip Fan Belt for Fords

Cork Insert Products Exhibited at New York and Chicago Shows

One Dollar for 1917 Fords
85c for preceding models

Authorities say that up to 50% of the "drive" goes to waste from slippage in the ordinary Ford fan belt. It gets so hard and glassy that the fan speed is reduced, the engine is not properly cooled and overheats. Cork Insert Fan Belts do not slip—they keep the fan fanning, keep the engine cool, are very long lived and economical.

Dealers: Order Cork Insert Transmission Linings and Fan Belts from your jobber. Ask him how Cork Inserts are moving. He will tell you they are a BIG WINNER. Stock them—recommend them—push them. They will make you a lot of profit.

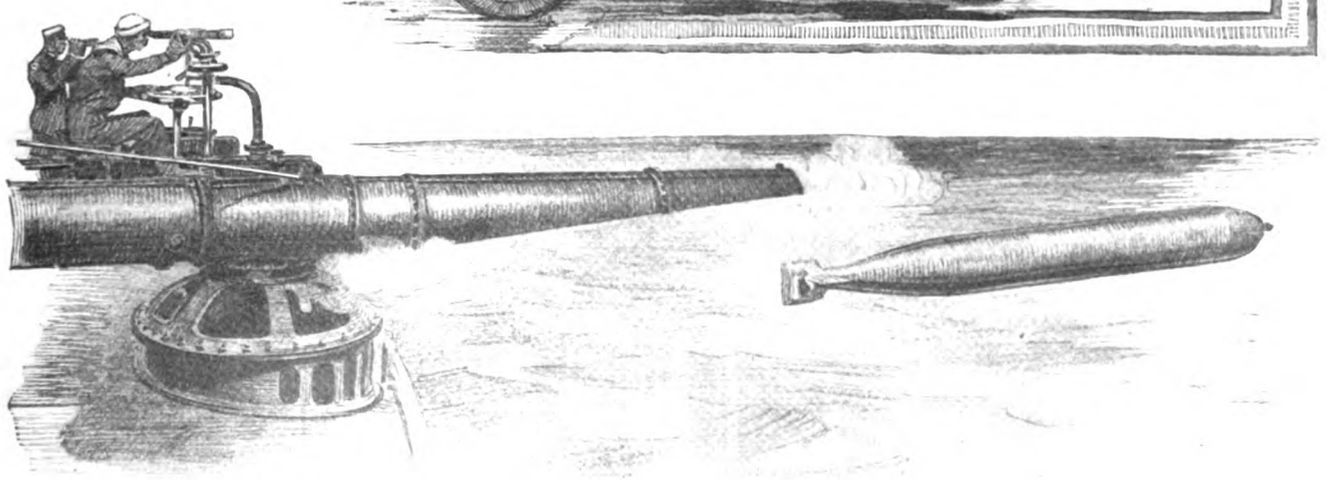
The Miracle of the Ball Bearing

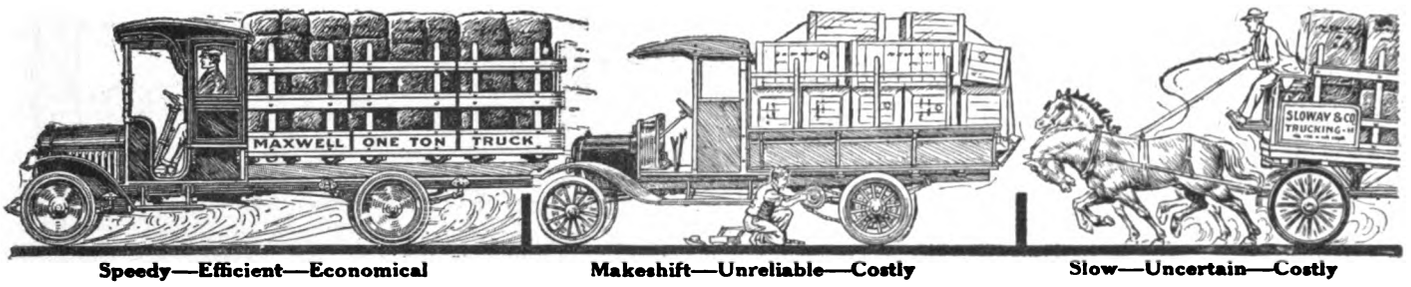
ON earth, sea and clouds man masters Nature by harnessing her own forces. He takes her own power and thereby rules her. Whatever saves power, increases its effect. The conquest of friction is a prime engineering victory.

No other form of matter rolls as easily as a sphere. New Departure inventors have applied this principle so ingeniously and successfully that great mammoths of stationary power plants and also the fastest of "far-darting" machines employ the supreme economy of



NEW DEPARTURE BALL BEARINGS

New Departure Ball Bearings are remarkable not only for their saving of power, but also because they are size for size stronger *than any other type of bearing made.* And the same factors which make them strongest and "smoothest" also make them the most durable.



Your machine, whether it is a great tractor or a fine electrical instrument, would ask you for New Departure Ball Bearings if it could talk. The evidence in our free book *does* talk. Please write for it.

Speedy—Efficient—Economical | Makeshift—Unreliable—Costly | Slow—Uncertain—Costly

Reach Quick for This Sudden Flood of Truck Money

Don't stand there, waiting another week, and watching this big profit opportunity roll past you.

They must have trucks. They are all waking up to it at one time. The whole trend of up-to-the-minute transportation science is sending business towards the dealer who has Maxwell One-Ton, Worm-Drive Trucks.

The one-ton unit is now recognized as the key to the solution of the problem the country is facing. The traffic experts' standards of 1916 are not the standards of today.

Country — town — agricultural — mercantile — industrial — bus — express — long haul — short haul — few stops or straight run — steady volume or fluctuating volume of traffic — no matter what the work of your district is, no matter how many different forms of traffic are being handled, the one-ton truck is the key to the problems that people in your district will have to cope with.

And of all the one-ton trucks the one that gives maximum service, at minimum cost, is the Maxwell Truck with the time-tried Maxwell engine and the same durable, reliable type of worm drive as in trucks costing $5,000.

The Maxwell is pure truck design and truck construction in every detail—steels of automobile quality, but not a transformed automobile. It carries a ton and at the same time can haul three tons.

Write for our offer to dealers while these trucks of maximum efficiency are still procurable.

ANDERSON SIX

Convertible Sport Car

Changeable in a twinkling from real roadster to real 5-passenger touring car

Prices

Sedan Convertible	$2,100
Convertible Sport Car	1,395
Touring Car, with straight front seat	1,395
Touring Car, with divided front seat	1,395
Victoria Top	150
Houk Wire Wheels, extra	100

Brief Specifications

Continental Six Motor—*Zenith* Carburetor—*Westinghouse* Lighting and Starting System—*Connecticut* Ignition—*Borg & Beck* Clutch—*Gemmer* Steering Column—*Columbia* Axle with Noiseless Spiral Differential Gears.

120 Inch Wheelbase—Semi-Elliptic Underslung Spring Suspension—Rear Springs 56 inches long—Weight 2750 lbs., ready for the road.

Regular equipment: There is a *Boyce* Motometer, a *Kellogg* Engine Driven Tire Pump, a *Stewart* Speedometer, a *Utility* Combination Heater and Foot Rest, a Muffler Cut-out, a Semi-Victoria One-Man Top of *Rayntite*, Quick Inside Attachable Storm Curtains, a *Klaxon* Warning Signal, *Duff* Jack and Complete Set of Tools.

Digitized by Google

The most *useful* car of them all

THE Anderson Convertible Sport Car is, we believe, the greatest utility car of the year, for it offers the buyer of a single car the use of two entirely different models—touring car *and* roadster.

It will be either—just as the owner desires and whenever the occasion requires.

As a touring car it is roomy and exceedingly comfortable — complete in every particular. It will accommodate five grown people without the slightest crowding or cramping.

Entrance to the tonneau is by an aisle between the divided front seats. The seats themselves are luxuriously wide and soft, tailored in real leather, French pleated. The top—a Semi-Victoria type—covers both the front and rear seats, just as it should. A UTILITY Combination heater and foot rest is provided for cold weather driving.

Or would you drive a roadster to-day?—then just fold the rear seats, tonneau and all, entirely away out of sight. It's a matter of seconds and requires no effort.

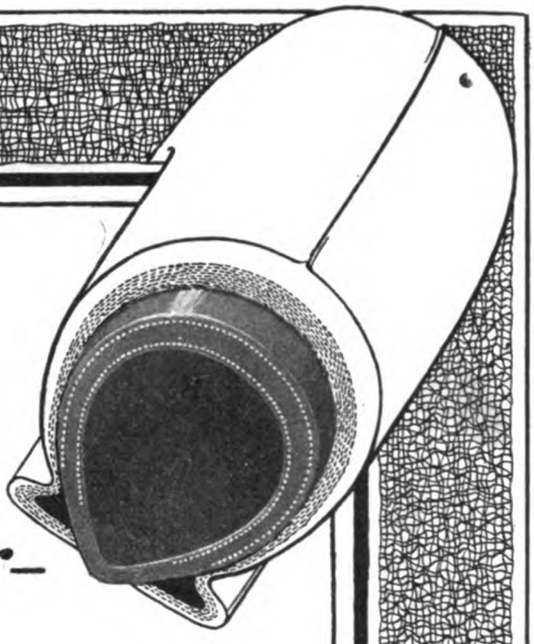
Now, in place of a tonneau, you have a graceful sloping deck of the smartest and most fashionable design. Underneath you will find liberal storage space, completely dust proof and lockable, for any amount of luggage, wraps and the many things such as two would carry "en tour."

Thanks to its pleasing individuality and refinement of design, it is a car that invariably commands favorable attention. It looks like a custom built car, *and it is.*

All Anderson Bodies are custom built in our own big body plant, where we have specialized in the production of fine coach work for 28 years.

As a result Anderson bodies possess a pleasing individuality aside even from the originality of their design. The bodies are more substantially built—more carefully constructed, less subject to rattles and metallic rumbles. The finish is more lustrous and lasting. It is hand applied and hand rubbed—a finish ordinarily used only on the most expensive custom built bodies.

As for performance, the Anderson SIX will do all the things any stock SIX will do. All of the mechanical units used are of nation-wide reputation—everywhere regarded by motor wise men as the finest.



It has more speed than any amateur driver should use. It will average 16 miles to a gallon of gas. It will throttle down to two miles an hour on high. It will take hills more easily than most cars you see. These are the things any Anderson owner will tell you, or things you can prove for yourself.

Dealers: Here is a car with which to meet war-time conditions. It possesses just the extra margin of chassis value needed to outstrip competition and stands in a class by itself when utility is considered. Some territories still open. *Descriptive literature available and will be mailed on request*

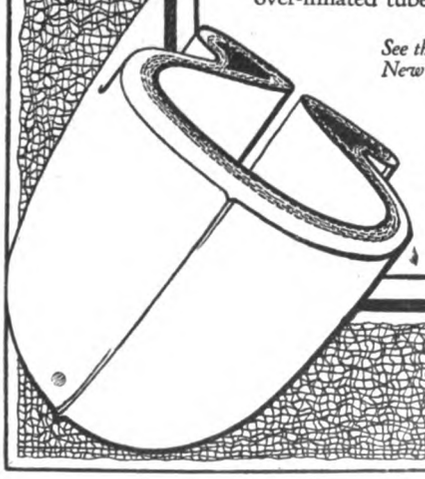
Five Million Motorists Are Waiting For—

Sternwear

—the Practical Tube!

It is many times as thick and consequently many times as strong as the old style wafer-like tube you now are using.

Its fabric reinforcing prevents expansion, except under the protection of the rim, and absolutely *prevents blowouts.*



Its neutral, (non-expanding), self-closing rubber provides a defense against the cause of ninety per cent of *punctures* common to the old-style tube.

Its adequate and proper inflation with fifteen per cent less air pressure *provides cushion* not possible with the old style over-inflated tube.

Its non-expanding, blowout-proof, puncture-preventing construction holds the air, and *holds the cushion.*

Its exactness of size and predetermined fit to the casting cavity *prevents trouble from friction heat.*

Its sturdy construction holds it intact regardless of a weak or worn casing. You can take a plain or non-skid tire, wear it down to the fabric, or carcass, put a STERNWEAR tube in it and that worn casing will give you equally, or more than, as much road service as it was intended to give you when you bought it new.

See the Sternwear Reinforced Pneumatic Inner Tube Exhibit at the New York Automobile Show, Grand Central Palace, Spaces D4 and D5; Coliseum, Chicago, Space 17B.

TRADE BRASS CO. MARK U.S.A. U.S.A.

PUMPS

FOR more than twenty years Bridgeport Pumps have been the leading tire pumps on the market. They lead because they are the best pumps that engineering skill and unlimited manufacturing facilities can produce. They are the only pumps manufactured complete under one roof, from the ingot to the finished product. Made by the largest manufacturer of hand pumps in America.

A selection from the Bridgeport line is assurance that you have a good pump—one that can be relied upon in any tire emergency—seamless drawn brass barrels—rust proof, non-leakable joints—an easy-working, built-for-service, dependable pump. No matter which Bridgeport model you select, you will find it a reliable pump, and the best value for the money you spent for it. Bridgeport Pumps have been supplied in the factory equipment of hundreds of thousands of cars.

Improved Aeolus

Bridgeport No. 16

Improved Aeolus—A powerful, double-action pump with two heavy, seamless drawn brass cylinders. As strictly high grade, efficient and durable a pump as can be made.

Bridgeport No. 16—A high grade, single-action pump. The heavy seamless drawn brass cylinder is 1½ x 17 in., providing the greatest volume of air per stroke of any single-action pump on the market.

Crown—A very serviceable single-action pump for small size tires. Heavy, seamless brass cylinder, 1¼ x 17½ in.

Crown

No. 4575—Combination Grease and Oil Gun—A powerful well made gun that handles all grades of oils and greases. Seamless drawn brass cylinder. Has removable screw tip for oil. Invaluable around the car and garage.

We also make many other types of pumps and grease guns. Write today for catalog.

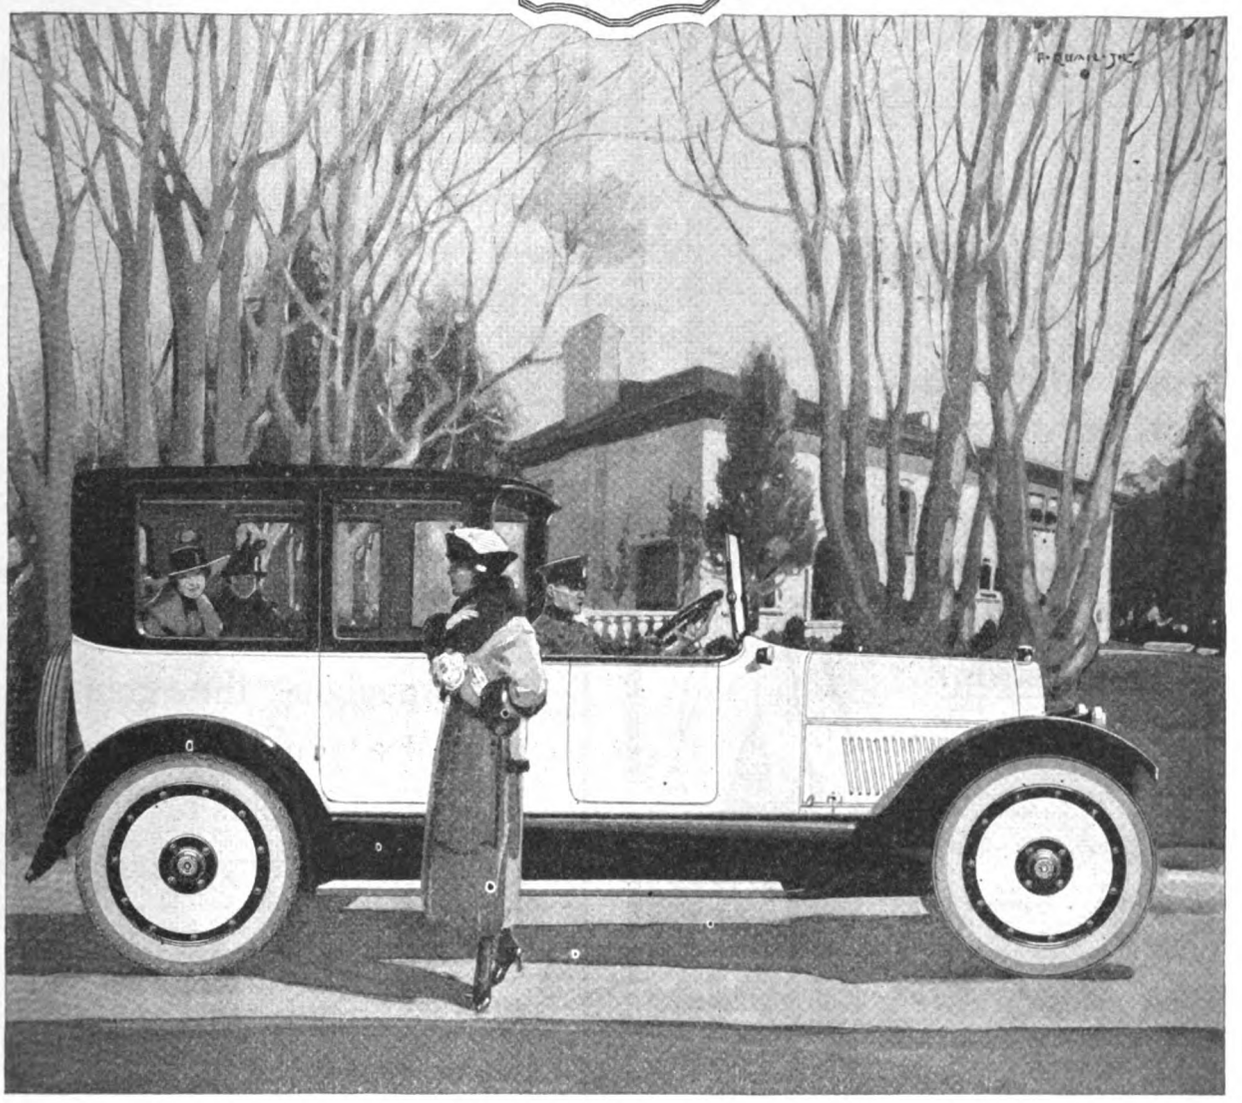
VANADIUM GEARS

CENTRAL STEEL COMPANY'S CHROME-VANADIUM STEEL

BY sheer force of superior merit, Vanadium steel has won its way as the standard of quality for Gears.

Convinced by their own tests, one after another of the leading pleasure car and truck manufacturers have abandoned steels which they have been using for years and adopted Vanadium Steel Gears.



The unequaled combination of strength and toughness, of which the accompanying illustration gives graphic proof, coupled with exceptional machining qualities, have overcome every opposing argument, every doubt and have established the economy of Vanadium Steel Gears from the standpoints of both service and production.

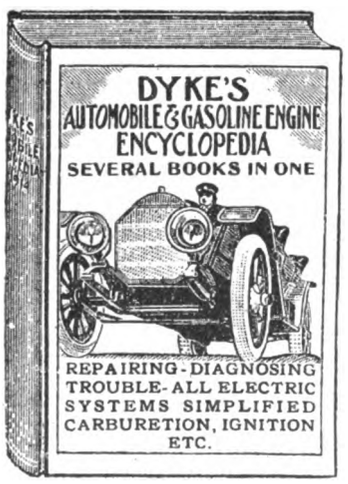
Automobile and Aircraft Instruments
ALIGHT AT NIGHT

without wires, batteries, switches or any personal attention.

MARVELITE

Provides continuous, practically permanent self-illumination of all instrument dials. It meets Government requirements. The basic light element in MARVELITE is radium (and radium only), the preparation containing a sufficient amount to generate a steady glow, lasting for many years.

MARVELITE is produced from formulas of the Schlesinger Laboratories, largest producers in the world of pure radium. It should not be confused with the short-lived phosphorus preparations which require exposure to light.



MANUFACTURERS: The luminous dial is of vital interest to the public, because of added safety and convenience. It brings the equipment of your machines up to date, and helps sell them. It is a necessity on aircraft, automobiles and motor boats. Insist upon having instruments that are "MARVELITED."

We will either sell the material to the manufacturer or apply it to his dials. Sample dials and hands prepared and estimates furnished upon request without charge.

The uses of Marvelite are too many and varied to be fully covered in this space. Send for Booklet No. 2 for information of importance to you.

DYKE'S AUTOMOBILE ENCYCLOPEDIA

STILL $3.00 or $3.32 Prepaid

1918—Sixth Edition

900 Pages—3362 Illustrations—6000 Lines of Index

Entirely re-written and illustrated—Many new subjects added—Practically a new book—Larger and better than ever

It is not what you would term an Encyclopedia in the time sense of the word—yet with its 6000 lines of Index there is not a trouble remedy or repair the Automobile is heir to that can not be found.

This book will teach one the Principle of Construction of an automobile from the axle to the engine. Every leading Clutch, Steering, Brake, Axle adjustment is fully covered.

How to Repair and Overhaul every part of a Car is a feature of this book. There are 1189 Illustrations and 154 pages devoted to the Repair Subject. Oxy-Acetylene Welding; How to equip a shop; How to use tools and make repairs, etc., thoroughly covered.

Electric Ignition, Starters, Generators fully treated, including care, adjustments and repairs. There are 279 pages and 775 illustrations on electric systems.

The Storage Battery Subject not only includes the principle of construction—but how to repair and test, etc., is fully covered. There are 46 pages and 162 illustrations on this subject alone.

Supplements: There are two; one on the Ford and one on the Packard, part printed in two colors. The Ford supplement not only covers the principle of construction and all repairs and adjustments, but such subjects as how to convert a Ford into a racer; and commercial car; how to get more miles per gallon, etc.

Inserts—There are 5 colored inserts in addition to the 900 pages. One of the inserts is something entirely new and original.

Order this book to-day—now—and see for yourself just what a valuable book it really is.

Aviation, Truck and Tractor Engines will be clear to you when you complete this book.

PIERCE GOVERNORS

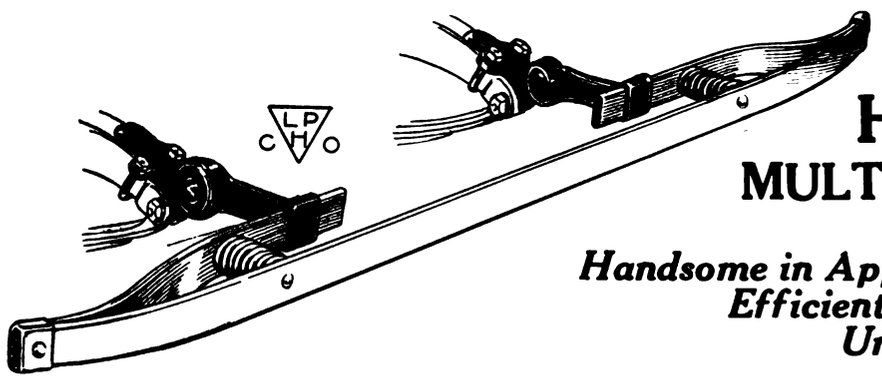
The Truck Industry's Chosen Standard

A RELIABLE speed limiting mechanism is as necessary on trucks, taxicabs and all commercial vehicles as rubber tires or steel springs. Excessive motor and tire wear, excessive maintenance cost, and 76 per cent of all accidents and collisions are the results of fast driving.

Pierce Governors limit the speed without limiting the power of the vehicle. Trouble-proof and fool-proof. All adjustments sealed. Approved by the U. S. Government for use on Army Trucks.

Regular Equipment on Sixty-seven Different Makes of Trucks

The best proof of the efficiency of Pierce Governors is found in the number and standing of the truck manufacturers who use them.



Don't let any manufacturer persuade you to sell trucks equipped with a governor that is "just as good." Demand Pierce Governors and your customers will be boosters for you, instead of "knockers," and will not be continually demanding unnecessary and unprofitable service on their trucks.

The Pierce Governor Co.

World's Largest Governor Builders

Anderson Indiana, U. S. A.

The Triumph of Bumper Construction

The New HALLADAY MULTIPLE SPRING BAR

Handsome in Appearance
Efficient in Action
Universal in Attachment

Supplied with special fittings as shown or with any fitting of the HALLADAY Line

The shock resisting qualities are derived from a combination of three steel spring bars and two heavy spiral spring buffers. The spring ends are joined by a hinge connection which eliminates breakage at this point.

Experienced dealers and car owners will quickly appreciate the enormous strength and efficiency of this bumper and the wise ones will get busy.

BREMER

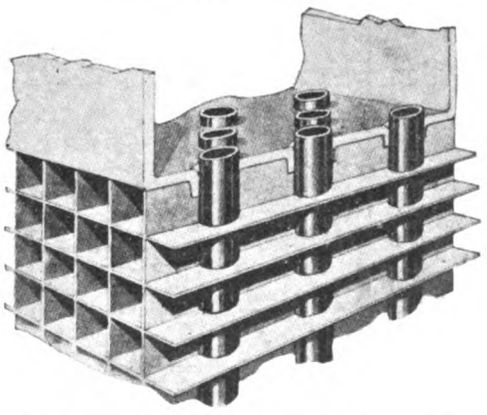
Fin Tube Type Radiators Serve Best For Motor Trucks and Tractors

Because—

They permit the use of a header plate or sheet punched and flanged, to fit the tubes perfectly. By brazing, a perfect permanent joint is secured at this, the critical point in radiator construction.

The round tube in connection with fins is the strongest possible construction of core.

The tubes are protected and proof against any injury except most violent impact.



The straight round tubes are free from clogging, a most common source of heating.

Their efficiency is equal to any type, and appearance is most attractive.

Bremer radiators are the highest development of the fin-tube type, which predominates in all heavy duty service.

Write for complete details of scientific principle today.

BREMER RADIATORS ARE ECONOMY RADIATORS ASK US WHY

CABLE LE ROI MILWAUKEE

Uniformity in Brake Lining

is just as essential as even flow of power from the motor. One starts and keeps the car going smoothly—the other controls and stops the car effectively but without vibration. Both are necessary in the well built automobile.

RUSCO BRAKE LINING

is uniform. It is woven on special looms built in our own shops. These looms represent the accumulated experience gained through three-quarters of a century in weaving—an experience that has taught us how to make Rusco so uniform that even when it is worn down to less than an eighth of an inch it still gives the same sure, even grip on every point of its breaking surface.

Several car manufacturers have used Rusco brake lining as standard equipment for a number of years. If you haven't, we would like the opportunity to furnish samples for test and also the services of our engineering experts on any special requirements.

Also makers of

Clutch Discs—Cone Clutch Facing

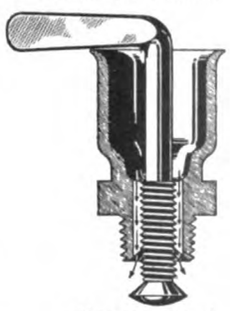
The Kant-Klog Primer

is rapidly being adopted as standard equipment by automobile builders because—

it is an innovation of efficiency and low cost—

it solves the problem of cold weather starting to the entire satisfaction of the user and can't clog with carbon because of its very construction.



The simplicity of the Kant-Klog Primer is seen in the sectional view. No part of the valve is exposed. There is plenty of clearance for the free flow of gasoline direct without waste when priming. There is no chance of carbon getting past and collecting on the seat. There is no need of removal even after months of non-use.

The more Kant-Klog is used the better its seating action.

Quotations on variations of our standard design to suit different type motors—promptly furnished.

Kant-Klog prices are surprisingly low.

Write today for particulars and free sample.

CONTRACT WORK

Advertisers in This Section Have Facilities at Their Disposal to Take on Additional Work on Contracts. Automobile Specialties of All Kinds Manufactured on Contract Basis. Special Machinery, Metal Spinning, Press Work, Auto Machine Work, Foundry Work, Automatic Screw Machine Work.

THE SOLUTION OF THE INDUSTRIAL PROBLEM

THE one thing that looms ahead of every manufacturing establishment is the shortage of factory space, equipment and skilled labor.

Every ounce of industrial energy will be called for in the work which lies before the Government of the United States and the necessary business to be done in addition to the Government's requirements.

In this section you will find announcements of a number of organizations provided with thoroughly skilled labor and proper equipment of machinery, capable of taking care of work which you must necessarily secure from outside sources.

In effect, these pages offer you an opportunity to add thousands of square feet to your factory space and hundreds of thousands of skilled mechanics and machinists to your productive capacity.

These organizations are doing for other manufacturers just the kind of work which would be most valuable for you.

FOR special work, for skilled and accurate manufacturing on contract, in the solution of some of your productive problems, this section represents a directory of concerns who have the organizations and capacity at your disposal.

A Remarkable Engine

For small Pleasure Cars, One-Ton Trucks and light Farm Tractors the ELBRIDGE STANDARDIZED Motor is an ideal power plant.

It develops tremendous power for its size, uses a very small amount of gasoline, and is practically never out of order.

It is well built, rugged, durable. **The Elbridge double lubrication system** greatly adds to its life, efficiency, and economical performance.

It carries our full guarantee as to every part of its make-up.

E-S MOTOR

Elbridge Standardized

has exactly the same dimensions as the Ford engine. Most of its parts are interchangeable with Ford parts, making replacement easy and economical. **No other motor on the market has so many standardized parts as the "E-S."**

It can be run at any speed, from 150 to 2500 r.p.m.; has 3-point suspension and fits into Ford chassis without alteration; bell housing designed to take standard transmission and Bendix Drive for starter. May be equipped with carburetor of any standard make, and with an Atwater-Kent ignition system or magneto.

A 4-cycle, 4-cylinder motor, 3¾" bore, 4" stroke, 22.5 B.H.P.

Our experience of fifteen years in building high grade marine motors enables us to build a truck and tractor motor for constant duty, which will stand up and give real SERVICE. Write for our bulletin today.

Parts for more than two hundred cars. Detailed information and prices in our Golden Gate Catalog.

Hundreds of magnetos—various styles and makes, $3.00 and up.

LAMPS of all kinds—both new and old—50 cents a pair and up.

Better than 200 *radiators.*

Don't forget that "copper is copper." No rust, no wear out.

Thoroughly overhauled and tested in our Radiator Department.

Half price and even less on *everything.*

CARBURETORS—An immense stock at your own price.

A limited number of Starters and Generators. Write for prices.

REAR AXLES—More than one hundred and fifty. $10.00 and up.

Two and one-half tons of springs. We can fit your car at five cents a pound and up.

CRANKCASES of new quality at better than one-half of the old list. Remember that new list is much higher.

CRANKSHAFTS—20 cents on the dollar.

CYLINDER BLOCKS — Unquestionably good — not the scored and worn kind. Lower than the lowest.

GEARS—Both new and old. Over three tons. Finely cut of the finest steel—case hardened. Always half price and better.

WHEELS—One thousand, $1.00 and up. RIMS of every kind and description, and plenty of them. It's up to you. What's your price?

BEARINGS — $5,000.00 stock. Prices unheard of before.

COILS—Positively guaranteed 50% discount and better.

30,000 ft. floor space—full. Bargains awaiting you.

An immense tire factory—manufacture all sizes. Guarantee three thousand miles at less than fifty cents on the dollar. Write for price list.

Remember

When you deal with Wyckoff you are assured of 24-hour service, a square deal, and a money back guarantee, if goods are not satisfactory. **"Better goods at better prices."**

Save Money Without Sacrificing Appearance

In this time of nation-wide economy, are you finding ways of cutting costs—and still retain quality? One item of saving—and it's no inconsiderable part of motor equipment either—is

GLASS

We have a mighty acceptable substitute for polished plate; and whether you use it on closed cars, windshields, clock faces, oil gauges or what-not, you will find it optically perfect. It looks well, too—and of course it's very moderately priced.

Write us your requirements, and let us tell you why this glass will serve your needs so well, why it costs less—and all about it.

Manufacturers

Line Your Brakes with

ELEKTRA
ASBESTOS FRICTION

Your truck is judged by its every day performance, and in the process of this severe test the brake lining plays a mighty important part.

Remember, then, that in Elektra there is a certainty of dependability which, day in, day out, makes for the limit of service and satisfied customers.

Elektra is an interwoven fabric of asbestos and metal, chemically treated to combine the heat-proof qualities of asbestos with the high friction of an indestructible material. Made with the greatest care to exacting specifications.

Ross Gears

WHITE with age, but with a heart still young and body unwearied, Nineteen Seventeen comes to the end of his task, and, with eager confidence, Nineteen Eighteen takes the wheel. He knows that the Ross Steering Gear which made last year's labor lighter will likewise make it easy for him to steer the old world for the twelve months to come.

The Steering Gears that Predominate on Motor Trucks

have won this high place by the easy steering, safety and reliability which are guaranteed by ROSS design, and by the highest quality in materials and workmanship. One hundred and fifteen motor truck manufacturers, representing considerably over half the entire industry, use ROSS GEARS as standard steering equipment.

A Wise Man Never Questions Success

Only the fools do. And when a man or a corporation goes big be wise and admit it.

Do you suppose the great Maxwell success was "the work of the wind" or ability?

Can you question figures like these:

Maxwell dealers	MADE	*in 1913-1914 over*	$2,500,000
Maxwell dealers	MADE	*in 1914-1915 over*	$4,700,000
Maxwell dealers	MADE	*in 1915-1916 over*	$8,000,000
Maxwell dealers	MADE	*in 1916-1917 over*	$12,000,000

Then question not what is in store for Chalmers dealers since Maxwell has taken over the Chalmers business.

For like makes like, and they who have the rare skill of making money for one set of dealers are sure to make money for another set.

Already the Chalmers sales curve has begun to climb. Today it is the highest in Chalmers history at this time of the year. And since the Maxwell policies began to operate the increase in Chalmers business has been just 200 per cent!

A good many wise dealers are taking on the Chalmers line.

STANDARDIZATION

The Great Wars Greatest Lesson

CONTINENTAL MOTORS · Power that Serves the Nation · AMERICA'S STANDARD

The whole world is awakening to the importance of standardization, the guiding policy of the Continental Motor. Based upon the best engineering thought of both Europe and America, this motor embodies, in standardized form, the technical knowledge of our entire generation.

Scores of manufacturers of motor trucks and passenger cars, thousands of dealers, hundreds of thousands of owners, through Continental power, multiply their own power. They thus bear living testimony to Continental efficiency and confirm its title as America's Standard Motor.

Strain, Stress & the Insides of Your Car

S-F ATLAS LUBRICANTS SPECIALTIES

THE strain and stress of winter service tests the fitness of every automobile or truck.

If there is something wrong with your motor you know it—there is a knock.

But how about the many other parts that have no audible means of warning you of impending danger, from strain and stress and lack of attention?

Left unattended, the inevitable happens. Cars become rattly, grumbly—they stall. Service is below par. Repair charges mount up.

The service given by a car or truck depends on correct lubrication.

Scientific lubrication protects the motor, protects the bearings, protects every point where metal rubs against metal. Whether the temperature be at zero or in the nineties scientific lubrication maintains at all times a protective film, essential to prevent wear. It absolutely keeps metal surfaces **apart.**

Scientific Lubricants for Scientific Lubrication

SWAN & FINCH COMPANY NEW YORK

Quality Oil and Grease Products Since 1853

NOW READY—Learn the interesting and vital facts about the insides of your automobile or truck. Write for "The Insides of Your Car"—a valuable booklet just issued by our Engineering Department—free for the asking.

To select accessory dealers and garages, an opportunity is open for a permanent, profitable connection with the Swan & Finch Company, for heavily advertised quality automobile lubricants.

Write for details. S-F Automobile Div.

For Motor Cars and Boats

GEARESE A correct transmission and differential lubricant. It insures a silent, smooth-running car, by preventing worn and noisy gears. It follows the gears continuously, leaving no spots where metal can rub against metal. It is unaffected by temperature. It lubricates instantly and constantly.

CUPESE A high quality cup grease for all machinery requirements. It adheres to bearing surfaces, is tenuous and elastic, positively prevents metal-to-metal contact. Made by the exclusive S-F Acaloric Process, making Cupese non-volatile—does not liquefy or evaporate under intense heat. It does not cake at low temperature. It outlasts ordinary cup greases.

MOTUL A superior quality oil for the lubrication of automobile motors. Made in a variety of densities to suit all requirements. It functions properly under intense heat—it leaves a minimum of carbon residue.

For General Use

CORUL A liquid binder that meets the 11 requirements of perfect core casting. (Automobile manufacturers—send for details.)

SLO-FLO The super-lubricant; will not drip, climb nor spatter, withstands excessive heat and pressure.

AERUL A practical high quality oil for aeroplane motors.

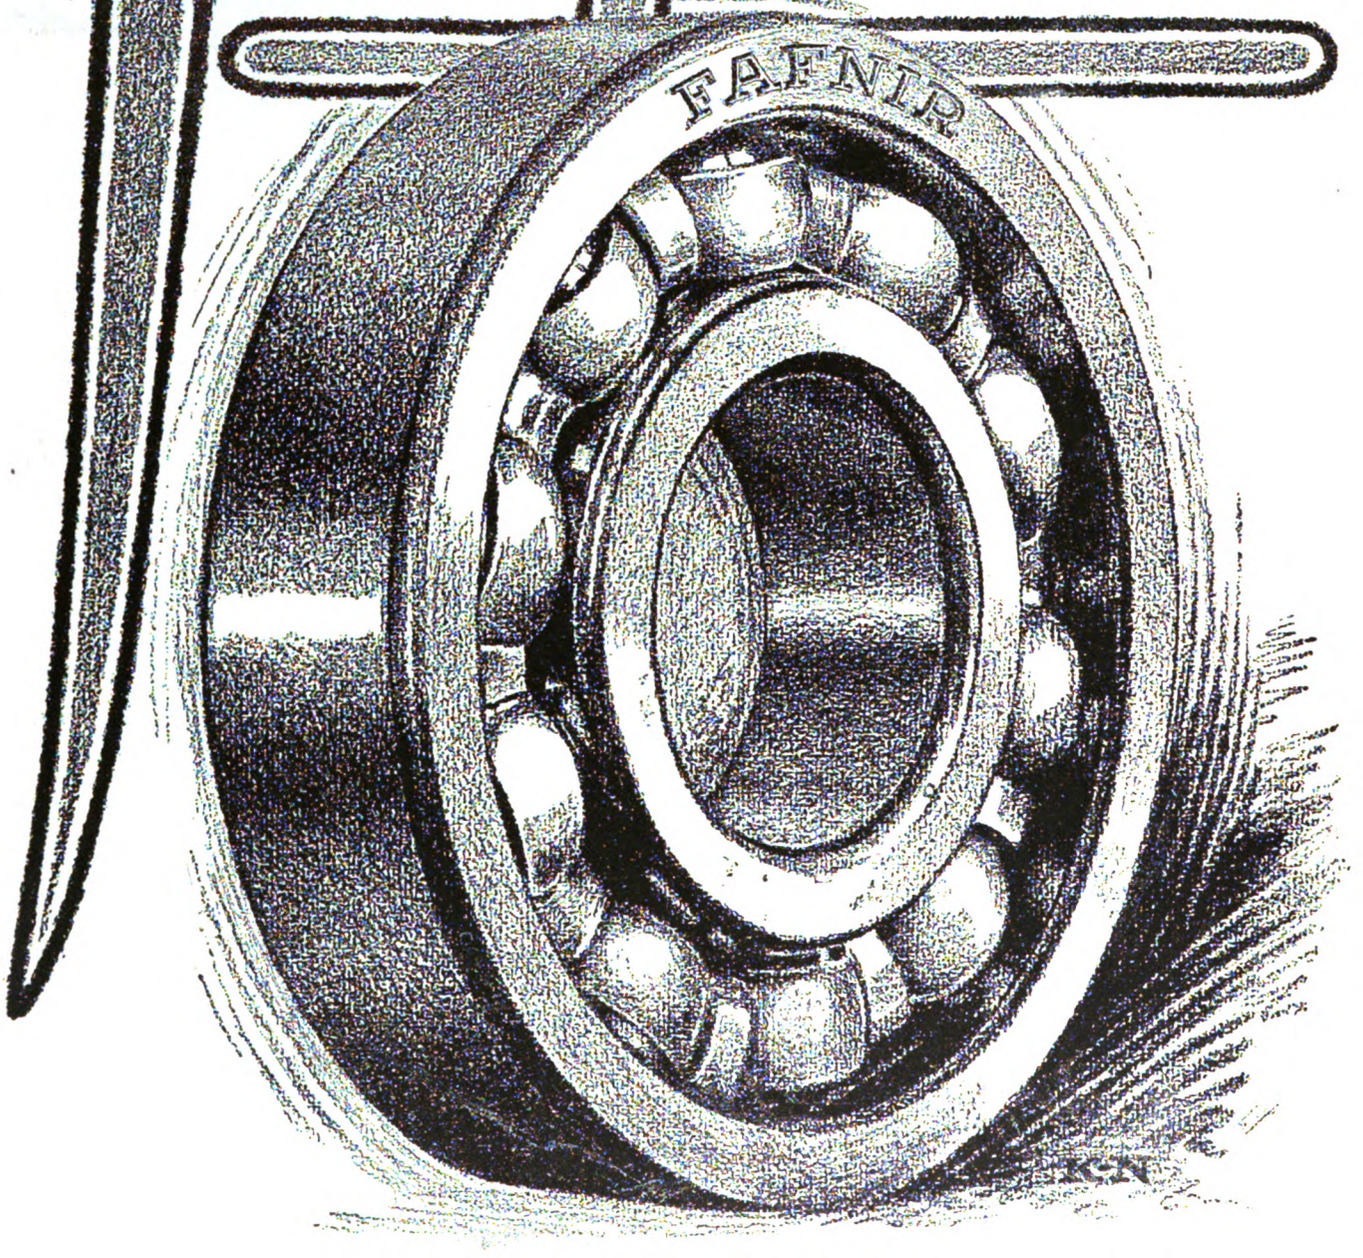
ASBESTESE An asbestos and wool-mixed grease lubricant for car journals.

MARINUL A world-known special oil, produced to meet the excessive stresses of marine service.

TEXTUL An economical, high quality oil compound for wool and worsted manufacture.

TALESE An economical, practical drop-forge die-swabbing grease compound.

EXESE The 600 deg. F. lubricant—for oven gears, bloom cars—calender rolls, automatic stokers—or lubrication under excessive heat conditions anywhere.



VESUVESE A waterproof lubricant for exposed gears—for cable dressing.

LARCUL A practical, economical metal-cutting lubricant.

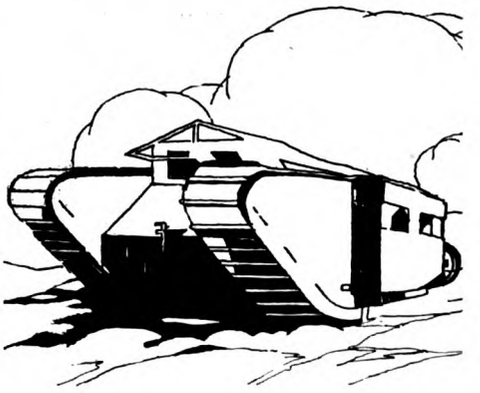
WYMAN-GORDON

TO YOU!



NEVER IN THE HISTORY OF THE INDUSTRY has there existed a more distinct *demand* for thorough efficiency, true economy, excellent production, than exists today.

IN THESE CIRCUMSTANCES, the absolute certainty offered by the Wyman-Gordon Guarantee is of far more than ordinary value.

LEADING MANUFACTURERS UPON WHOSE EFFORTS DEPENDS, in great degree, a full and early Victory for our military forces, have recognized this by putting their Airplane, "Tank," Motor Car and Truck forgings under the protection of that Guarantee.

We offer the same certainty, the same effective co-operation, to you.

VOL. XXXVIII NEW YORK—THURSDAY, JANUARY 10, 1918—CHICAGO No. 2

First War Show Justified by Success

High Character of Attendance and Growing Business Gratify Manufacturers—Dealers Studying Conditions—Southeast Strongly Represented

GRAND CENTRAL PALACE, New York, Jan. 8—The first war show of the automobile industry, now three days old and with four days more to run, has already demonstrated that in spite of the war the public is still deeply interested in automobiles and the show gives promise of demonstrating that war shows should be continued. The attendance has not been up to that of former years, but the weather previous to the opening was the coldest in 60 years, which, coupled with the shortage of coal, froze up New Yorkers as they have not been frozen up before in the present generation; and it is only to-day that the crowds that have filled the aisles and exhibit spaces have been on hand as in former years, though not in such great numbers.

What the attendance to-day has lacked in numbers has been made up in character, and the catalog collector and the usual paper following are not present and are not missed, because the dealers have enjoyed a better opportunity of looking over the cars and chassis to-day than they have for several years past. The aisles are not crowded in the forenoons; they are snugly filled in the afternoons and in the evenings. The jam is not like in years past, but the space is comfortably filled. No figures have been given out on attendance, but it is expected that with a continuance of good weather the crowds will not fall far behind those of former years.

The wartime crowds, if the attendance to-day may be so designated, are a little different from those of last year. There are fewer of the young men between 20 and 30 years of age that have been seen at these shows for years, and as the young men are not present there is a proportionate absence in the attendance of young women falling within the same age limits. To-day the persons visiting the show are older—more of those that carry their overcoats slung over their arm instead of checking them downstairs. There is not so much dress as a year ago. The crowd does not resemble a New York crowd in the sense of last year or previous years. It looks more like an out-of-town crowd, and it is. The crowd has a big percentage of dealers from the Southeast, the cotton states which are booming with cotton selling at 30 cents, the highest price since the Civil War. In the Southeast every farmer is in the market for a car, and the de-

mand for automobiles listing under $1,500 is greater in this section than ever before. The dealers from the Southeast are here in force. Many of them are placing more orders than they can possibly have filled for months.

The dealers, although a little later in arriving than in former years, are coming in in good numbers from other sections, such as New England and even the Middle West. New York State has large numbers, so has New Jersey, Connecticut and other states in the proximity of New York. Chicago has not so large a representation as in former years, but the most substantial ones are here and are going to remain all week.

Show the Opening Wedge of Year

The New York show is looked upon by most of the makers present as a kind of ice-breaking proposition, and as the opening wedge of the 1918 show circuit it is not seriously considered as a dealer show and is not ranked high as a retail show to the 10 per cent of the nation's population that might be said to reside in Greater New York and its environs. New York has been a strong retail show, and it will not do to become pessimistic if it is not this year. Locally New York is frost-tied worse this year than in any other year since the automobile inception in 1895. November and December are generally slow months in New York, and if they are as slow this year as last the trouble cannot be laid to the war, but to weather and general conditions. This year weather conditions have been unduly severe.

As a dealer show New York never has compared with Chicago, and the exhibitors are not expecting to get very close to the dealers, as they never come here in the numbers they come to Chicago, or perhaps Minneapolis or Kansas City or Boston.

The atmosphere within Grand Central Palace is not a subdued war atmosphere; more color meets the eye than at any previous show. This color is not splashed on a few intensified color studies of special show cars trimmed with white bridal ribbons and "keep off" signs, but is sprinkled through every exhibit, as substantial colors, such as grays, greens, blues, browns, carmines, buffs, yellows and reds. They are colors you can use on the street or road without being ashamed of them. They are inspirational colors, and it is indeed fortunate that sombre black has not been too liberally patronized. There are several exhibits of four or five cars in which there is not a single black model. In this list might be mentioned Franklin, Pierce, Velie and several others where only one or two cars are displayed.

Dominant Note of Newness

Besides a healthy variety of color, which is good merchandising in war times, and which is much more stimulating than black even if the colors are not perhaps so serviceable, there is a dominant note of newness in the show. It is not a "tale-that-is-told" type of show, but a show of new designs, some new cars and a few new names. The very general development of the straight-line, beveled-edge body has lent an atmosphere that is magnetic in that the new styles engender an interest that might be lacking if the body lines too closely resembled those of a year ago. Even if the chassis is that of last year, the body is like your new Easter hat. Its sharp corners catch the eye of the visitor who stops and is given an explanation by the salesman, thereby affording the desired audience which may eventually lead to a contract or a sale. It is good merchandising and the show would have needlessly suffered if this atmosphere of newness were missing.

Another aspect of newness is the sport four-passenger model. It is taking well in that it is attractive to the eye, looks considerably lighter than the five-passenger or seven-passenger touring model, and may be described as a war model. There are magnetics in just enough carrying capacity, in reduced weight, and in greater mileage per gallon of fuel this year.

A few makers have added a further touch by the disc wheel, which is with us for the first time. It carries very much of a war visage with its resemblance to the trusty warrior shield of the fifteenth century. There are enough new models such as the small Willys four, the new Studebakers, the Olympian, the Moore, and other changed models to keep up the interest and carry conviction to the visitor that the story of automobile development has not yet all been told and that many succeeding years will be needed before the final chapters of change will be written.

Smaller Advertising Campaign

The advertising campaign through the New York dailies has so far fallen 50 per cent behind that of a year ago. The amount of space is smaller. There are few full-page ads, very few half pages and none of the double pages of past seasons. A more careful expenditure of advertising appropriations is very conspicuous. A commendable feature in some of the advertisements is that they are more of a national nature, intended to carry conviction as to the essential aspect of the industry. John Willys has been a leader in this national sentiment. One advertisement reads: "What railroads are to the nation motor cars are to the individual." Another refers to the automobile as being the shortest distance between two points in the transportation field. These and similar brief messages should have a desirable influence at this time. In general the advertising copy carries quite a different message from that of a year ago.

As an accessory show the present exhibit is the biggest ever, if the expression may be justified. There are more exhibitors, but of a slightly different character. Each sees changes. The representation of pneumatic tire makers is very small. The gasoline storage tank maker that used to have space is not present this year at all. There is a dropping off of makers of parts such as ignition specialties, engines, axles, bearings, etc. There are a great many accessory concerns with small wares.

Unfortunately too few of these accessory makers take the arranging of their spaces as seriously as they should, and as a result the stands are not good places to do business. One maker has arranged his exhibit space into a sample room to display his com-

Digitized by Google

plete line for jobbers attending the show. Instead of all being piled on a counter along the front of the booth, there are inside aisles on either side of which are sloping tables well stocked with samples of the entire line. This allows the jobber to move into the exhibit, entirely out of the aisle and look over the line and talk prices with that necessary seclusion. More accessory men should follow this example and thus make the show more of a real business center, because each successive year finds the potency of the show more centered in its business value than in its value as a place to satisfy the curiosity of a catalog collecting attendance.

Dealer Wields Big Influence

The dealers are analyzing in a much broader way. They carefully scan the product itself and before going into the matter of taking up representation they are acquainting themselves with the factory resources of men, money and materials. In other words, the strong dealer has become a power and is one of the dominating influences in the business to-day. This is so true that it is often found that it is the big distributor that is shaping the policy of the concern which he represents.

Big distributors seeking to change their lines are in a stronger position this year than ever. They are using, for this very reason, the greatest of care in making connections and it is also because of this that the greatest care is being taken with business transactions at the show.

The lack of a great variety in the real low-price class is commented upon quite commonly by distributors. Cars in the $750 class which would be particularly adaptable to the Southern trade are not to be found on every hand as they were 2 years or even a year ago. These cars have not graduated to the $1,000 class, and consequently the amount of money that the dealer has to put up to secure what is now considered a low-priced line has considerably increased.

Visitors Interested in Motor Development

People who attended the show were experts in motor car development, generally speaking. The exhibitors who employed trained talkers at their booths did not fail to draw an exceptionally large crowd. These people asked a great many questions and these tended to show that development has been followed by the public with marked closeness.

Following a growing tendency of the New York Show, the bigger factory executives were not on the floor. They could be found at the Biltmore, Astor, Belmont, Woodstock, or any of the other large hotels surrounding the Palace. Here suites are retained and used as consultation rooms away from the confusion attendant upon the show itself. The Palace is the showroom and the hotels are the business offices.

Practically all the manufacturers represented at the show are keeping demonstrating cars outside. The new dealer who is looking into a product is demanding a demonstration as well as the retail prospect. In the past years some of the manufacturers have not kept the demonstrator car in mind as well as they should and it has resulted in the loss of interest on many occasions. At the present show the space outside the building of the Palace is quite well filled with the demonstrators of the exhibitors.

There are several South American dealers present and others are expected to be at the show during the week. Reports of the closing of agencies in Brazil have been made by one of the concerns and this same organization has been approached with reference to Japan. One of the factors which has affected this phase of the situation is the scarcity of bottoms, and foreign business is of course subject to the shipping consideration to such an extent that it is not receiving the prominence as regards certain countries that it would normally.

Realizing the demands of the public for cars which have economy as one of the strongest features, dealers themselves are subjecting the chassis exhibited to scrutiny along the same lines. The developments of the year along this line have been largely due to the requests of dealers for the best possible showing on any economy basis and this is being followed up directly by inquiries at the exhibition. As pointed out on other pages of this issue, in the new cars the overhead valve engine predominates to a marked extent and the reason for this given by the manufacturers who have brought out these cars is that with them it is possible to secure the greatest possible returns from a minimum size engine.

A Feeling of Earnestness

The playtime attendant of the show is missing. There are fewer banquets of a formal nature. The N. A. C. C. banquet is only one of a great number of the show-time functions that have been abandoned this year. There is a feeling of earnestness in the air. The new manufacturers are depending on the business done by them through the show circuit to put their propositions on the map. In fact, with some of the newest of the concerns it is a matter of securing dealers on the show circuit or stop their enterprise. The drop in sales in specific territories must be made up by a wider distribution of the product and there is a tendency of expansion among concerns formerly satisfied with a local trade.

Stimulation of sales by offering the buying public something new is always a part of show business and the show of 1918 is no different in this respect. On this occasion we find that the straight-line and the beveled-edge body are offered as a stamp upon the product that it is of 1918 vintage and different from what could be bought a year ago. The four-passenger car of what is known as the sporting type, the addition to the number of stock colors, the addition of improved types of convertible and closed bodies are all parts of the new features of the show. There is a marked appreciation for all of these features in the crowd which has attended during the earlier days of the exhibition.

The New Yorker is always looking for something which is different. Extraordinary features are what hold his interest; however, the car with the magnetic clutch or gearshift, the two steam cars, a front-driven vehicle, will always be surrounded by the crowd who come out of curiosity or to satisfy a craving for the mechanical.

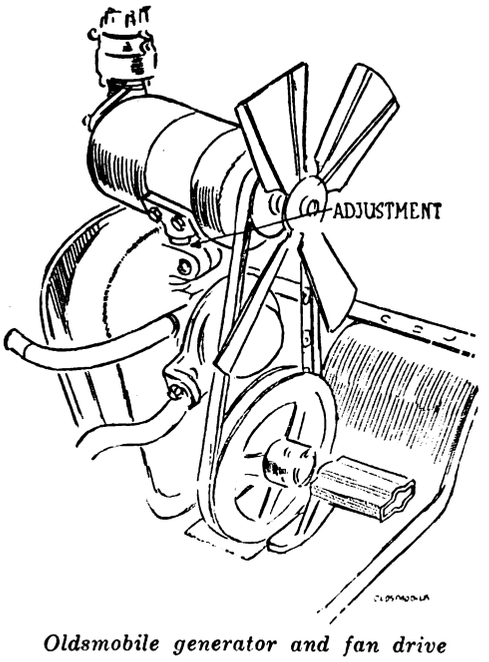
Mechanical Tendencies Revealed By the Show

Interesting Developments in Piston Design—Combined Accessories Drives—Front Exhaust Pipe Take-Downs—Neater Wiring Schemes—Transmission Locks—Overland Small Car Features

By P. M. Heldt

IT is not a difficult matter in going through the show at Grand Central Palace to get up a long list of mechanical changes made in individual cars, but there are few new tendencies in mechanical design discernible. The changes made from last year's models depend in a large number of instances upon individualities in design, and there are not many cases in which the same or similar changes have been made by several firms.

If there is any particular motive that has guided a majority of designers it is that of economy. For example, in the inclosed-car class the inside-drive type of body has greatly increased in number, the underlying idea being that many car owners who heretofore have employed chauffeurs will henceforth drive themselves, and the inclosed-drive type of body naturally makes a special appeal.



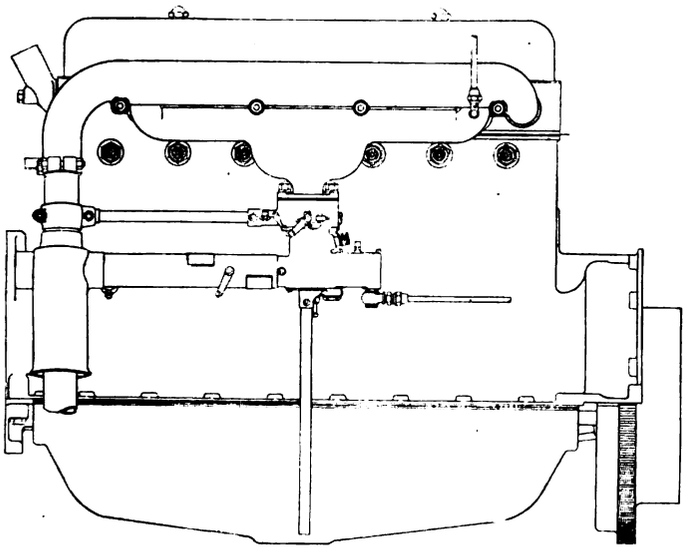
Economy the Keynote

The same object may be discerned in the substitution of oil cups for grease cups on spring shackles and other parts. Filling grease cups is a messy, tedious job, and if the owner has to attend to lubrication himself it is apt to be neglected. With oil cups in these places, of such design that they can be readily opened and closed, much of the drudgery of lubrication is eliminated.

In this connection it is not only the owner caring for his car in his own garage who has to be considered. Owing to the fact that an enormous number of young men have been withdrawn from the industries most garages in the future will have to get along with a reduced force, and the cars stored will only receive such attention as this reduced, and in most cases less experienced, force can give them.

In engine design there is a continued tendency toward separate cylinder heads, one of the latest converts being Cadillac. With such heads the decarbonization of the engine by scraping, which most garage men seem to consider the best all-around method, is greatly facilitated. Probably another factor that favors this construction is that it does away with valve plugs and the placing of spark plugs in them, which is a frequent cause of preignition. With the increasing engine speed and the decreasing cylinder sizes, there is a tendency to use as high compression as possible. The heavier fuels which must now be used having a somewhat lower temperature of ignition, every effort must be made to eliminate hot spots in the combustion chamber wall, and the elimination of valve plugs tends in this direction.

Those firms which have been building aluminum engines during the past year are continuing them, and this type of engine will probably see quite a boom when aluminum prices drop to normal again. The Premier has made an important change in its design, whereby the cast-iron cylinder liner is no longer surrounded by an aluminum shell, but is fitted to the aluminum casting with packings at top and bottom. This results in the cast-iron liner—which is machined all over and therefore of absolutely uniform thickness—being in direct contact with the cooling water on its outside. While with the old style of construction a clearance of 0.009 in. was necessary on the piston skirt, it has now been found possible to reduce this to 0.004 in. The advantage of this is twofold. In the first place it is well known that with aluminum pistons there is a tendency to piston slap when the engine is cold, this being due to the very considerable clearance which must ordinarily be allowed with these pistons. If the clearance can be cut down by more than one half, the cause of piston slap is largely, if not wholly, eliminated.



Oldsmobile generator and fan drive

Every user of aluminum pistons has had to content himself with the piston slap difficulty, and a variety of solutions have been arrived at. Probably every reader is familiar with the Packard plan of slightly offsetting the piston pin from the piston axis. Franklin slots its piston skirts lengthwise from the open end to the wrist-pin zone. This permits of a very slight clearance on the skirt, as the slots give the metal in the skirt a chance to expand without increasing the diameter and, therefore, without creating a tendency to bind.

While on the subject of piston slap it may be of interest to relate the argument of one stand attendant why his engines had never been known to develop this defect. He explained that most engines had the spark plug on the side, over the valves, and as the push of the gases started from the plug the force of

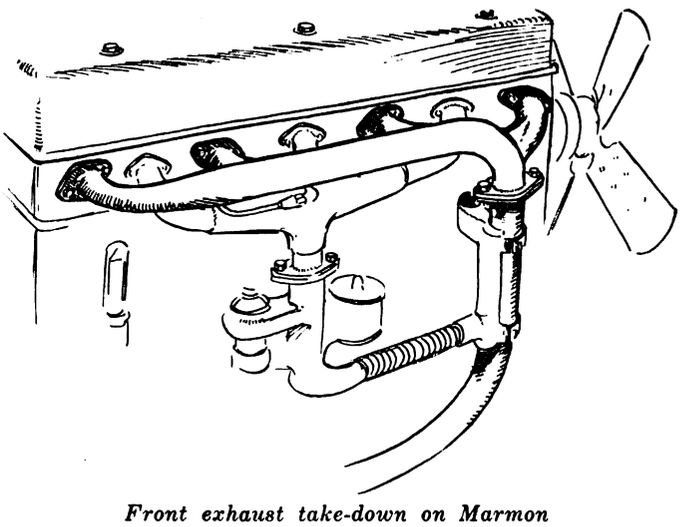
Digitized by Google

Front exhaust take-down on Nash

explosion came against the piston sideways and created a slap. In his cylinder the plug was in the cylinder head and there was, therefore, a straight down push on the pistons. This argument of the straight push on the pistons due to spark plugs in the cylinder heads has been met with repeatedly recently, probably as a result of the tendency to remove the plugs from directly over the valves to a more central position. It would seem that the scientific principle that within a closed vessel containing gas under pressure the pressure is uniform over the entire interior surface does not command much respect among car salesmen and catalog writers.

Relieving Piston Surfaces

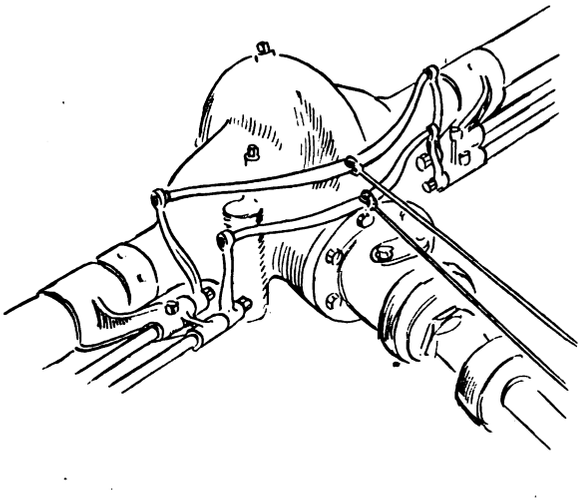
Another tendency in piston design is to relieve the skirts of the pistons on the non-bearing sides as much as possible. This is a new application of a principle long ago established in connection with journal bearings. In the average journal bearing carrying a heavy revolving part the load is carried at the bottom. Owing to the friction the center of the load, of couse, shifts slightly to one side of the line perpendicularly below the axis of the journal. There is no appreciable load on the sides of the bearing at the level of the journal axis and it was found advantageous to relieve the bearing at both sides over a certain area, so that there can be contact between the joural and bearing only at the top and bottom. The reason why this construction gives an easier running bearing is readily explained. If the journal were in contact with the bearing all around, the film of oil which must be sheared as the journal revolves would extend all around. The oil film at the sides does not reduce the unit pressure on the lower part of the bearing and its only effect is to produce a loss due to the shearing. In a piston the conditions are exactly the same. The pressure on the piston walls is greatest along the two lines of intersection of the plane of connecting-rod swing with the cylindrical surface of the piston. From these lines the pressure eases off toward both sides and there is no pressure midway between these lines. If a thin film of oil is allowed to exist between the piston and cylinder wall at these points of no pressure or little pressure, a considerable loss of power is incurred, especially in a high-speed engine and if a rather heavy oil is used. Aluminum cylinders cast in metal molds are generally cast with relieved surfaces, and pistons cast in sand molds are now often formed with similar depressions by turning them eccentrically. Formerly pistons were generally relieved on the wrist-pin belt by being turned down concentrically. This does not give as much relief on the sides as desirable and removes some of the useful bearing surface adjacent to the maximum pressure lines.



One of the perplexing problems that every designer has to contend with is that of accessory drives. The number of accessories has been constantly increasing and while there is no difficulty in finding a place and arranging a drive for each of them, there has recently been a strong tendency to clean up engines and chassis as well. It is very desirable that one drive be made to serve for two or more accessories, yet the possibility of an accident to one of these accessories interfering with the operation of the other must never be lost sight of.

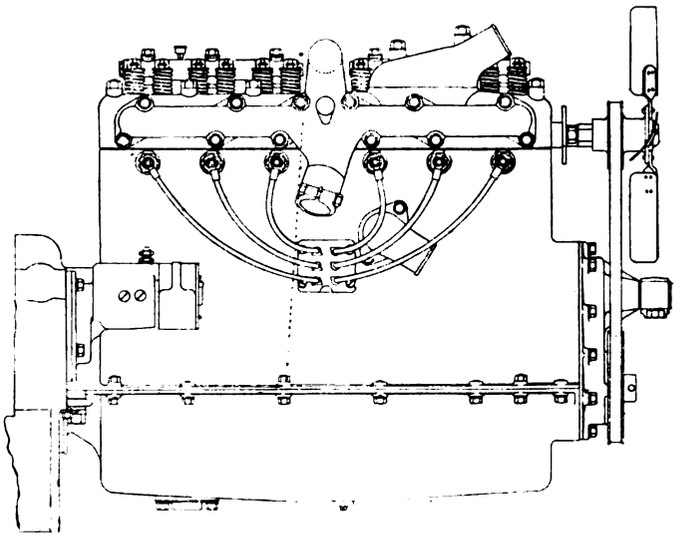
Fans on Generator Shafts

There seems to be a growing tendency to use the same drive for the generator and the fan. This practice originated with makers of eight-cylinder cars where the generator is placed in the V between the two sets of cylinders and naturally comes at about the right height for the fan shaft. It has now been extended to four and six-cylinder vertical engines. In the Oldsmobile the generator is mounted in front of the engine on a pad with a vertical stem clamped in a bracket on the cam gear housing. This provides adjustment for the belt. Nash uses a similar construction, but in this case there is a sort of base at the rear end of the generator with oblong slots through which pass clamping bolts to the cylinder block. In some instances where the fan is mounted on the generator shaft the drive pulley is in front of the fan. This results in quite a space between the fan and the radiator, which is not conducive to the highest efficiency.



Some years ago there seemed to be a tendency toward two-blade airplane type fans. The capacity of these fans in many cases proved inadequate and only a few of this type are left.

The subject of manifolds really merits an article by itself, as there are few concerns which have not changed their design in this respect during the past year. In a general way it may be stated, however, that the air heater is now not a separate part, but is incorporated in the design. Where in past years we used sheet metal or cast stoves clamped to the exhaust pipe or manifold, which connected to the carbureter air intake by a flexible tube that often ran half way around the engine, the air heater is now formed integral with the exhaust manifold and connects to the carbureter by a short length of either rigid or flexible tubing. The



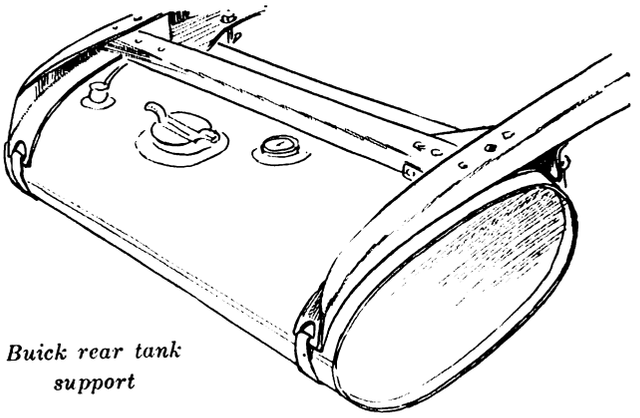
Front exhaust take-down on Marmon

Digitized by Google

Neat brake equalizer arrangement on Elcar

Symmetrical arrangement of high-tension cables on Grant

hot-air tube was especially obtrusive where the carbureter was located on the opposite side of the engine from the exhaust pipe. Where this is the case the pipe is now generally carried through the space between the two middle cylinders.



In a few cars the circulation pump and fan are both driven by the same belt. As in the case of generator and fan, the speeds of these two devices are about the same even if driven separately, and the pump combines more readily with the fan, especially in a six-cylinder car, because it occupies less space in a lengthwise direction. Some people, who had experience with early cars in which the pumps were driven off the flywheel, might object to a friction drive for this important part, but there is no comparison as far as reliability is concerned between a modern V belt in an inclosed engine space and a friction drive from an exposed flywheel at about the lowest point of the car. There is one merit in the friction drive for the circulation pump, namely, that if the latter should be allowed to freeze up it cannot be broken in cranking.

Reducing Height of Cars

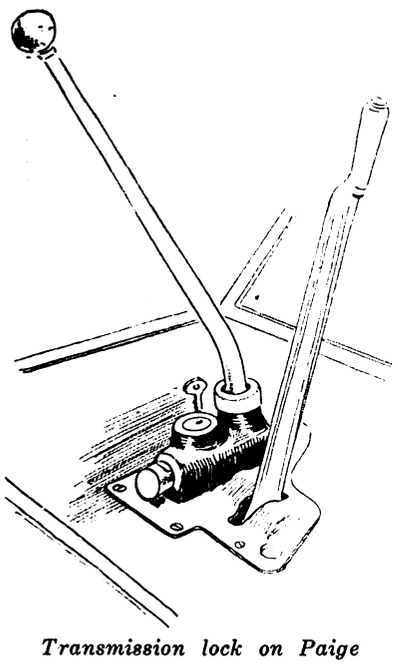
The tendency toward low-hung construction continues, the incentive seeming to be chiefly a desire for more attractive appearance, though the advantages of greater safety (stability) and steadier riding qualities cannot be disputed. This year the chief change looking toward this end has been a reduction in wheel diameters. Many cars that formerly had 34-in. wheels are now equipped with wheels of 32-in. diameter. This change, of course, also conduces to economy in construction and just in what proportion the economy factor and the appearance factor share in the responsibility for it, it is hard to say. To further reduce the center of gravity of the cars the rear springs, if of the semi-elliptic type, are now generally underslung.

In recent years the unit power plant has been strongly in the ascendency. The first sign that this movement may possibly come to an end may be seen in the new Studebaker chassis. This is probably the first instance in years of a passenger-car manufacturer having adopted an admidships transmission and discarded one differently located. The reasons for this move are not far to seek. Bell housings contain a large amount of metal, which means a heavy expense if aluminum is used and great weight if—as is more customary in low and medium-priced cars at present—cast iron is the material of construction. The inclosure of the flywheel and a dry-disc clutch serves no useful purpose, but the fact that the bell housing holds the bearings of engine and transmission in rigid alignment has been an important consideration in the past. The use of a pair of universal joints between the clutch and the transmission obviates the need for such alignment, but the usual types of joints are rather complicated mechanisms and, moreover, they have a tendency to become noisy with age. Noisiness is a particular fault of the simplified types of joints, such as the Hookham joint, which the designer is tempted to use here on account of the small angularity required. So long as only mechanical joints were available engineers seemed to prefer the bell housing. Now, however, the leather or fabric type of joint has reached a manufacturing stage and seems to fit this service admirably. It is comparatively inexpensive, is noiseless and requires no attention. The advent of this type of joint in commercial form swings the balance of advantages in the direction of the separate transmission, and it may possibly return to popularity.

A little detail of construction noted on the new Studebaker is in connection with the brake pedal. Most brake pedal shanks extend substantially straight up from their hub for a certain distance and then turn forwardly to follow the inclination of the toe board. At the point of the bend a lug is formed on the shank to which the brake rod is connected by a yoke. In the Studebaker (as well as in several other designs) there is a separate arm on the pedal hub for the brake rod to fasten to, and in order that this arm need not be made very heavy it is braced to the shank of the pedal.

Buick rear tank support

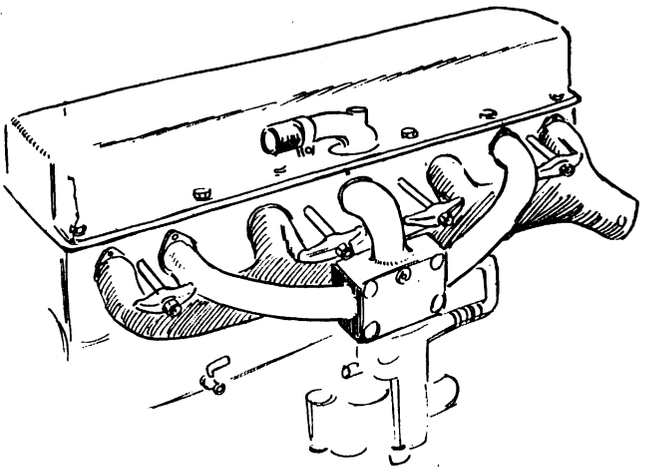
Digitized by Google



The metal in the brace is almost in direct tension when the brake is applied, and therefore works to the best advantage.

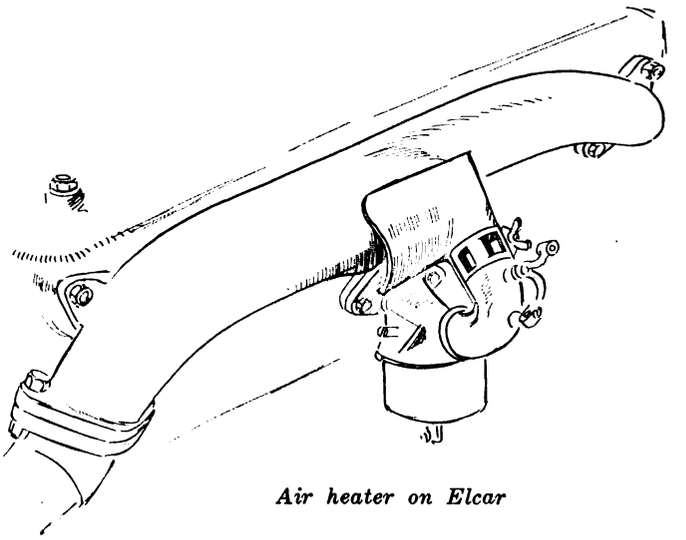
In line with the general tendency to clean up chassis design the ignition wiring in some cars has been rearranged. In some of the lower-priced cars the wires were carried from a distributer at one end of the engine to the different spark plugs across the tops of the cylinders. This involves the use of quite long high-tension cables, with corresponding chances of leakage and of trouble from electro-static effects, especially if the cables lie close together. Probably the chief objection has been, however, the unsightly appearance. This is now being attended to and the accompanying sketches of the Grant and Oakland high-tension wiring show examples of neat arrangements without the use of conduits. By placing the distributer at the middle of the length of the engine, variation in length of the different cables is reduced and a neat effect can be obtained.

Gear Lever Locks



Gear lever locks are gaining. Formerly cars were locked chiefly by switch locks. However, the great prevalence of a few popular makes of magneto and battery ignition systems, and the fact that only one form of key is being used with each ignition system, make this protection rather illusory. Fuel line locks have also been developed and met with a measure of success. An objection to both switch locks and valve locks is that a skilled man can easily make connections to the engine from a separate current source or fuel supply. On the other hand, if the gear lever is locked in the neutral position, apparently the only way to move the car is to tow it.

Rear fuel tanks are becoming more numerous right along and the various methods of supporting them afford quite a study. A particularly neat arrangement is found on the Buick, where the tank is of flat oval shape and is located substantially centrally below the rear cross-member of the frame. The frame side bars extend beyond the rear cross-member and are curved downward to conform to the outline of the tank. The top flange of the side bar is cut off on a bevel beginning at the cross-member, and where it ends the web of the side bar begins to be reduced in a similar way, so that finally only the bottom flange remains. This has a slot cut through it near the end through which the steel band used to support the tank is looped. The other end of the band connects to an eye bolt which passes through a hole in the lower flange of the side bar and is drawn up by a nut. An integral gusset is formed on the side bar where it joins the rear cross-member and this gusset has a flap on it which bends up on the rear side of the cross-member and is riveted to it.



Transmission lock on Paige

It is getting to be quite a common practice to lead the exhaust manifold down at the forward end of the engine. Early instances of this arrangement may be traced back a great many years, but its development into a regular practice is quite recent. When the steering gear and exhaust manifold are located on the same side of the engine there is apt to be interference if the latter is carried down at the rear end, and this probably was the original *raison d'etre* of exhaust manifolds with front take-down. It is quite likely that such a manifold and exhaust pipe arrangement also favorably affect the engine efficiency, as the cylinder exhausts into a long pipe of large volume and excellent cooling facilities. Owen, Marmon and Nash are some examples of engines with a front exhaust take-down.

Hot spot manifold on Scripps-Booth

Air heater on Elcar

In past years one of the most annoying things on automobiles has been the fan belt. Belts will stretch and require frequent adjustment, especially if rather small in size for the work they have to do. This trouble has been partly eliminated by using more liberal belts, still the constantly varying belt tension as the belt stretches with atmospheric conditions, and as a result of wear makes for anything but ideal operation. The Buick company this year has adopted an automatic tensioning device as shown in the sketch.

Probably the most interesting exhibit to visitors of a technical turn of mind was the new Overland small car which is to sell at a popular price. It has often been said, and correctly, that at this late date it is not a difficult thing to design an automobile which shall give excellent service; the difficulty begins when it is required to design the car so that it can be produced at

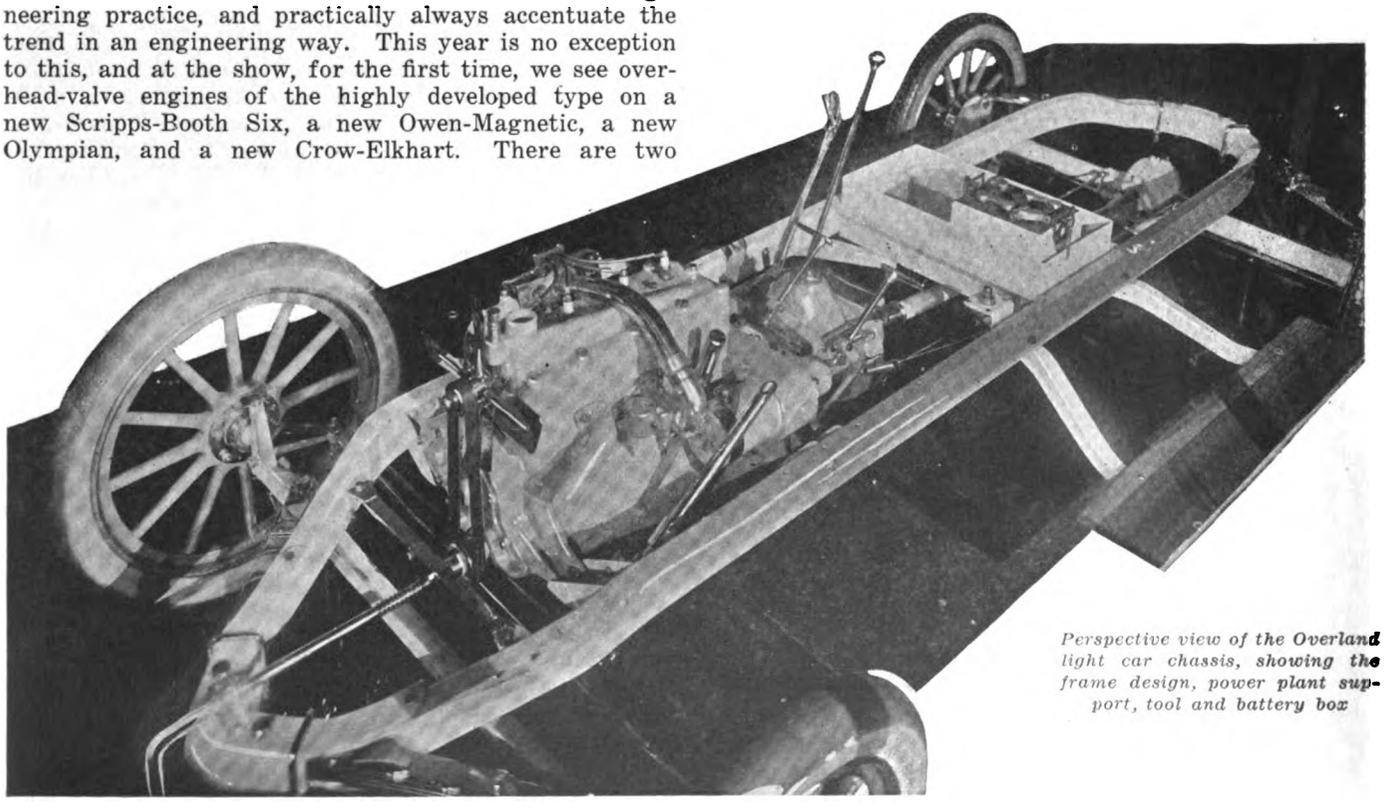
Production and Economy Features Characterize New Cars at Show

Valve-in-Head Type Indorsed by Makers Who Are Using Show as Occasion to Announce New Models

By J. Edward Schipper

ANALYZING the new cars at the show, the conclusion cannot but be made that an unqualified indorsement has been placed upon the overhead-valve engine by the industry. There are five cars which have never been shown before using this type of power plant, and two others using the L-head design. One of the latter, the new Overland Four, is not as yet in production, and probably will not be for some months.



Of the new cars present there is no doubt that the Overland Four takes a prominent position in general interest because this is a car which Willys-Overland is soon to launch in competition with the Ford. Its price has not been fixed, but it is understood that it will be on a competitive basis with the Detroit product. Consequently, it is designed to be made on a highly organized production basis in order to bring the possible selling price down to the lowest limit.

Surprises Not Numerous

While the number of show surprises is not nearly so great as in former years, the new cars have a more significant value. New cars are, in nearly all cases, the results of careful study, particularly as regards the possibilities of placing them on the necessary class-production basis. These cars are also indicative of the latest engineering practice, and practically always accentuate the trend in an engineering way. This year is no exception to this, and at the show, for the first time, we see overhead-valve engines of the highly developed type on a new Scripps-Booth Six, a new Owen-Magnetic, a new Olympian, and a new Crow-Elkhart. There are two L-head engines, both of them on low-priced cars, the new Overland Four, which will probably sell for close to $500, and the Moore 30, at $695.

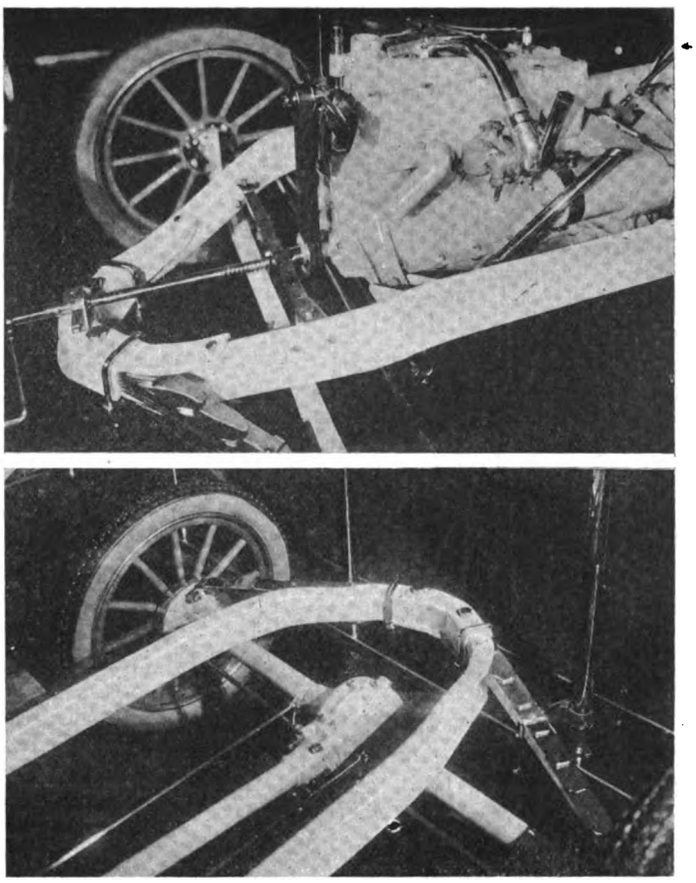
In addition to the new cars there are always new bodies added to present chassis, and exhibited for the first time. This is particularly true this year, where a surprisingly large number of new bodies has been added as sales stimulation. Hupp is now exhibiting its complete line of closed bodies on its new chassis. Oldsmobile shows a new sportster. Cole exhibits its bevel-edged bodies for the first time. There are a new Liberty limousine, a new Elgin sport model and a convertible sedan. McFarlan has a sportster of rather extreme lines. There are also a great number of special show bodies which are not regular products, but exhibit cars.

Besides the cars which are new throughout, either in chassis or body, there are a great number which incorporate refinements made within the last few weeks. This is the case, for instance, on the Winton, where a new water-jacketed intake manifold is fitted, and on the steam cars, both Stanley and Doble. The Stanley car has a number of important refinements in the piping, and on the Doble the fan is now operated by a small impulse turbine of the velocity type, actuated by exhaust steam. The Peerless cars now have L-head engines in place of the

Perspective view of the Overland light car chassis, showing the frame design, power plant support, tool and battery box

Digitized by Google

overhead-valve type, although otherwise the design is quite similar. This is one example where a manufacturer has gone from the valve-in-head to the L-head engine. This change is to a great extent due to the advantages of construction on the V engine.

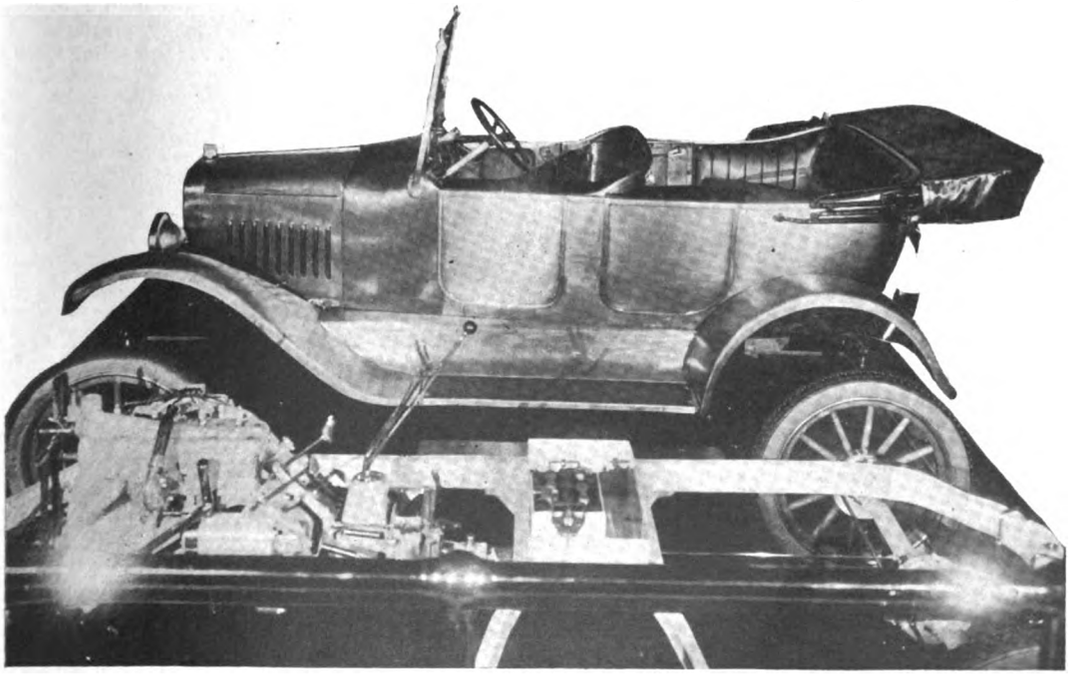


Willys-Overland Exhibits Forerunner of Low-Priced Product

Will Be a Big Production Car with High-Grade Engineering Features

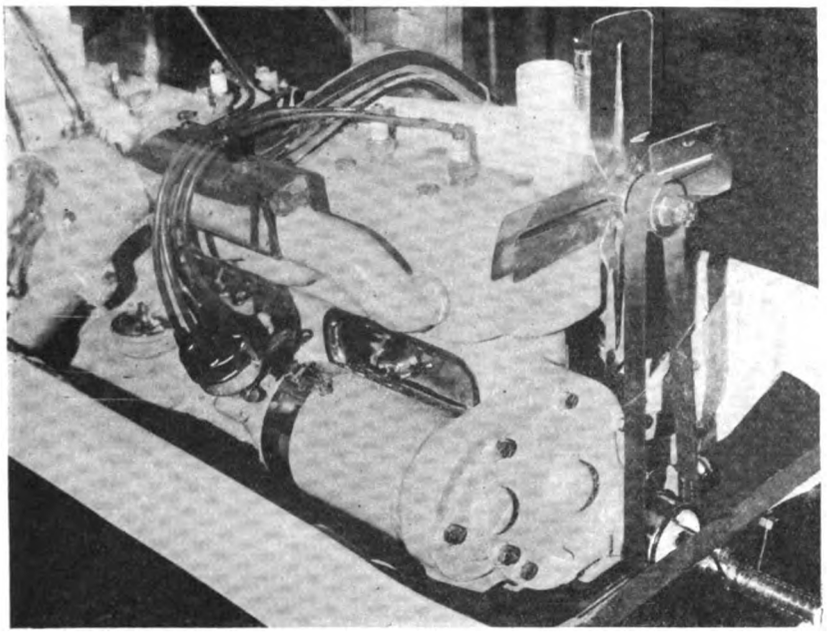
THE Willys-Overland big-production, low-priced Four, shown for the first time three months ago at the Toledo factory in chassis form to a few inside observers, is exhibited as a chassis and an unfinished body. Its predominating feature from a construction standpoint is the skillful use of pressed steel in both chassis and body. Everything possible is made as a pressed part, giving the desired lightness and low cost. Another feature is the extension of the chassis suspension forward of the front axle and behind the rear axle by the means of an overhanging form of spring arrangement.

The result is that the Willys-Overland company has produced a 1500-lb. car on a wheelbase of 100 in. with the equivalent of 130 in. in spring suspension. The frame side members are long pressed steel parts, spaced quite closely, the distance from the inside of the channel side on one side to the inside of the opposite channel being 23 in. The depth of the channel member is 31.2 in. and the width across from the outside of the channel flange on one side to the outside of the channel flange on the other is 26 in. These side members are rounded off front and rear so that the form of the chassis frame is what might be roughly called a flat sided, narrow, continuous ellipse, the ellipse itself being 130 in. from end to end.



As the wheelbase is 100 in., the front and rear axles are both 15 in. in from the ends of the frame, this amount being represented by the overhang of the chassis. The springs are mounted in such a way as to connect the overhanging ends of the frame to the axle, this being accomplished by a horizontal V-type of suspension at both front and rear. The front springs being fixed at both the frame and axle and the rear springs being shackled on one side and pivoted on the other to take care of the movement of the body, thus the front axle member is relied upon to absorb directly the spring stresses by slight movements of the front axle from the vertical.

Front and rear ends of Overland light car chassis



Outside of the radical departure from usual practice in the arrangement of the frame members and suspension, the Willys Four does not depart from standard design in its other features. A conventional type of block L-head four-cylinder engine is used with dimensions of 3¼ by 4 in. The valves are operated from a gear-driven camshaft through mushroom push rods. Cooling is by thermo-syphon and oiling by a pressure-feed system in which the oil is thrown by centrifugal force by the flywheel through an oil strainer and then to a lead to the hollow crankshaft. The hollow shaft also takes care of the lower connecting rod bearings.

The castings for the engine are arranged in accordance

Sheet metal body alongside of chassis of Overland light car. The ensemble is surrounded by a railing to keep the crowds at a distance

Digitized by Google

Four-cylinder L-head engine for the new Little Four Overland

with practice in L-head design. The head is removable and the cylinders are cast in unit with the upper half of the crankcase. This casting also carries the motor supporting feet at all four corners, giving a four-point rigid suspension. The water jackets are large, and in connection with a cellular tube radiator with a large tank at the top the cooling system hold a total of 7 gal., which is much larger than that employed in cars of far greater size. In connection with this radiator there is a fan driven by belt from a gear on the end of the crankshaft, and the tension on this belt is constantly maintained by a spring.

A complete electrical system is employed. The units are the Auto-Lite for starting and lighting, and the battery equipment may be either U.S.L., Gould or Willard. The battery capacity is 60 amp.-hr. The motor and generator are mounted separately, the generator being on the right side and driven directly from the timing set, while the starting motor is on the left and is engaged with the flywheel by the Bendix gear.

Unit Powerplant

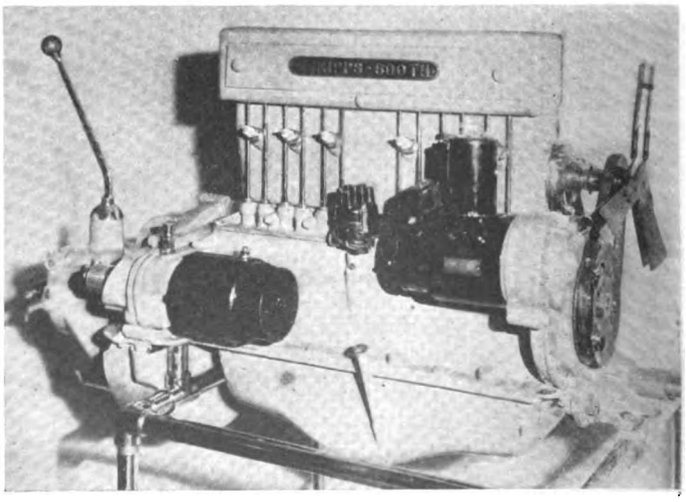
The clutch and gearbox are mounted with the engine as a unit powerplant. The clutch is an oil disk, having three disks faced with Raybestos. It is housed within the flywheel and secures its oil from the engine, the same oil lubricating the entire unit plant, flowing back also to the gearbox, which is a three-speed, sliding, selective. From the gearbox the drive passes through one universal joint to the propeller shaft and thence to the three-quarter floating rear axle. This axle is a single bearing floating type with a ball bearing pressed over the outside of the axle housing, carrying the wheel, and a roller bearing at the differential end. The wheels are wood, carrying 30 by 3½ tires, non-skid in rear. Propulsion is through a torque tube.

Two sets of brakes are used, the foot brake being mounted on the jackshaft, giving a transmission brake, with the hand brake on at the rear wheels. The control members for operating the brakes and controlling the other functions of the car are placed in the customary manner.

The body is a production job as well as the chassis, being pressed steel throughout. The type shown is a five-passenger job and arranged with an apron-like projection in the front and a rounded off rear to accommodate itself to the overhanging frame suspension. The running boards are supported from the chassis by two inverted pressed steel U-bars riveted to the frames, giving a substantial support to these boards. The color of the body is not fixed, and there are some other details which are also to be settled upon before the car is put into production. For instance, the gear ratio on the model shown is 4.73:1. This may be altered, and the color is not as yet fixed upon. It is expected that a definite move toward production will be made during the coming spring.

Scripps New Six Has Northway Overhead Valve Engine

First Appearance of This Make as a Five-Passenger Touring Car

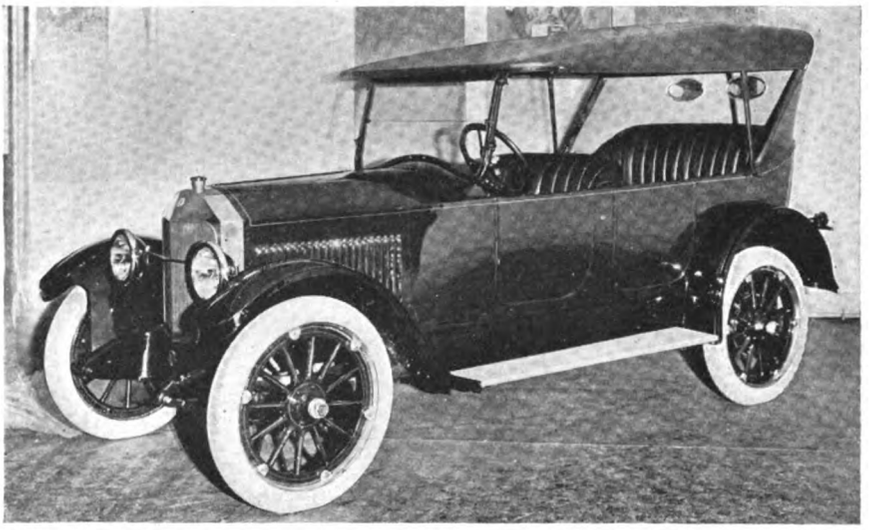


FOR the first time the Scripps-Booth car appears in six-cylinder, five-passenger form. The familiar body lines which have created a name for distinctiveness remain, although they are modified to accommodate them to the new touring model. The new Scripps design is due without doubt to the definite inauguration of this concern as a part of the General Motors Co., and General Motors units displace the parts which were formerly purchased elsewhere. This is particularly true of the engine, which is now the Northway overhead valve six.

The new car which is sold as a five-passenger for $1,195 is mounted on a wheelbase of 112 in. It is equipped with a 2 13/16 by 4¾ unit powerplant, having its six cylinders cast in block, with the valves operated from a single camshaft which actuates a set of exterior side rods and then an overhead rocker arm valve set. The cylinder heads are detachable and are held in place by long studs, and there is in addition a coverplate which incloses the valve action in order to give dust-proof qualities and silence.

The intake manifold on the new engine employs the hot plate principle in order to aid in the evaporation of the mixture. The manifolds are on the right side of the engine, and the exhaust from the two central cylinders is directly against the portion of the manifold around which the intake gases are led. The carbureter is a Marvel, and is provided with a full hot-air intake so that both the primary air and the mixture are subjected to the high exhaust temperatures.

Pump on Fan Shaft



Pump cooling is used, the water pump being driven off the fan belt, as both the fan and pump are on the same shaft. The belt is a notched type to give positive drive. The fan is what is known as the biplane type, being a three-blade unit, with each blade having two parts parallel to each other in the form of a biplane. Starting and lighting and ignition is by the Remy system, and the oil feed is by means of a Stewart vacuum tank in connection with a rear gasoline tank.

Scripps is now using the Northway valve-in-head six-cylinder engine

Digitized by Google

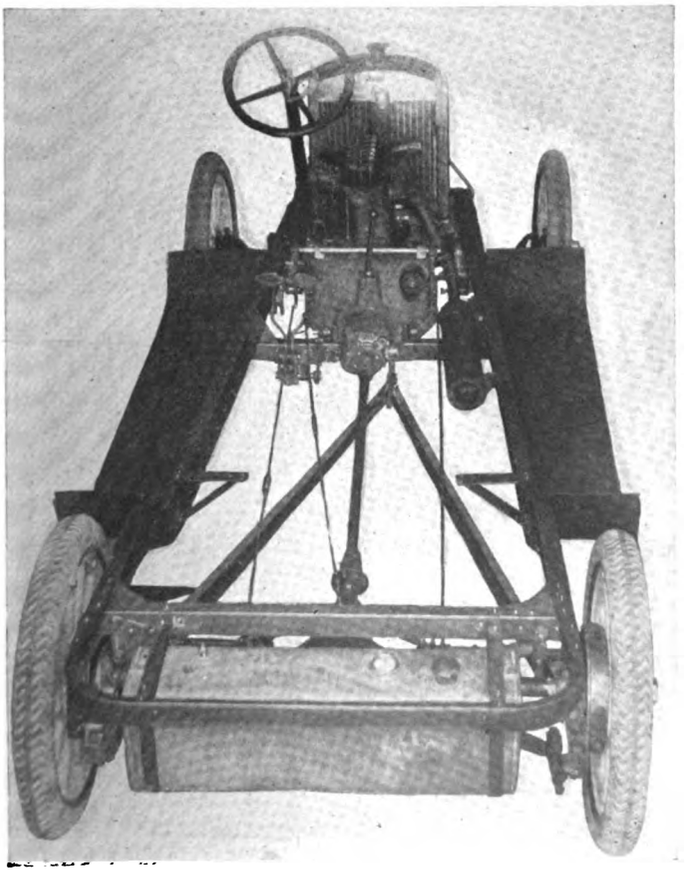
Power is transmitted through a clutch faced with leather, having an aluminum cone with spring insert. The gearbox is a Warner-Munsey type, with ball bearings on the main shaft and plain bearings on the lay shaft. The propeller shaft has two universals, and the drive is by the Hotchkiss system in connection with semi-elliptic springs. In addition to the equipment mentioned the list price includes Marshall upholstery springs and a Stewart speedometer.

Five-passenger touring car mounted on the new Scripps six-cylinder chassis

New Olympian Uses Brush Deep Frame Chassis

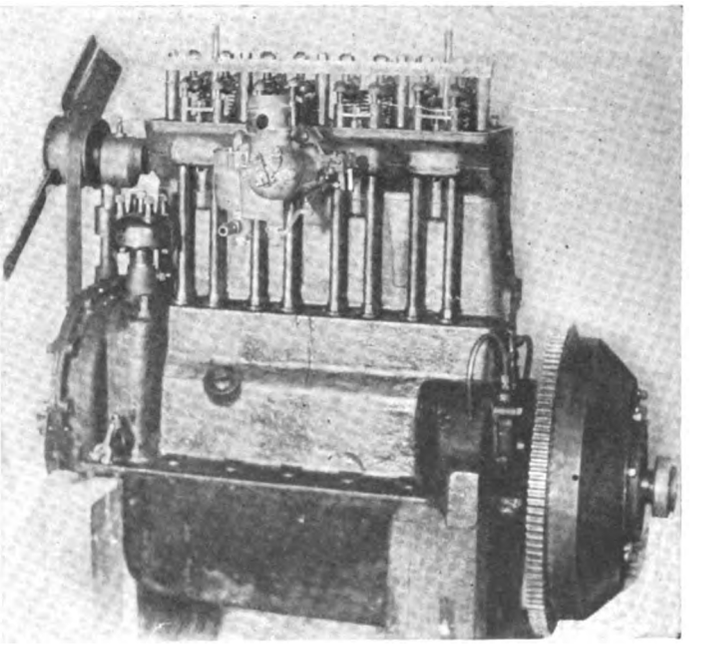
Has Overhead Valve Engine—Light-Weight Construction Features New Product

THE Olympian Motor Car Co. of Pontiac, Mich., is exhibiting the first of its new cars. This is a new design throughout and incorporates Brush features such as the valve-in-head engine, deep frame construction in which the side members are formed by the splash apron and the running boards are also part of the frame structure, the full circle housing on the rear axle and the related features which go with this type of construction.



In addition to these features the drive units have been made stiffer by a triangular layout composed of two torque arms coming together at their forward ends, so that an equilateral triangle is formed by the two torque members and rear axle.

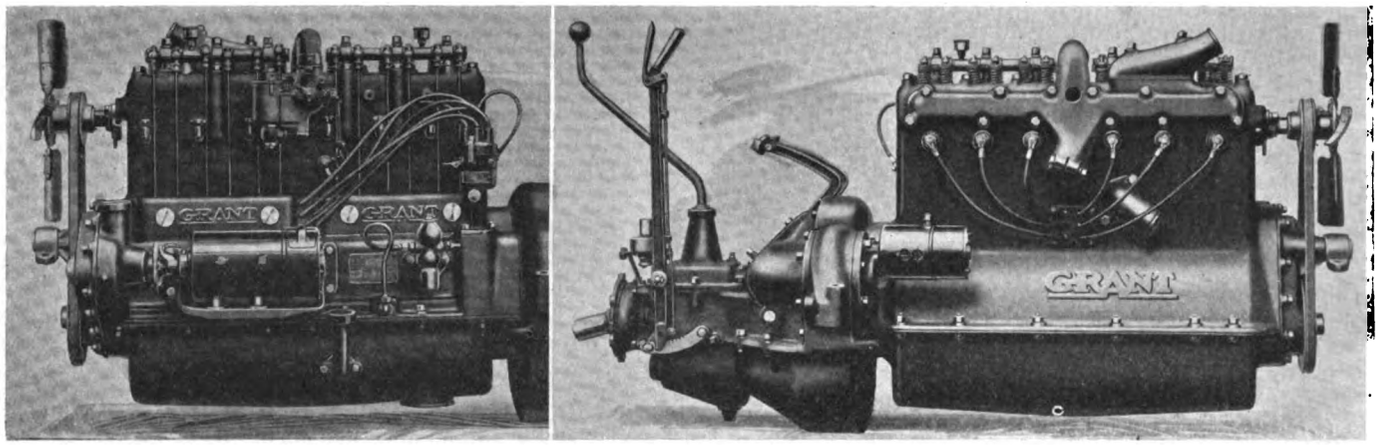
Mounted on a wheelbase of 112 in. the body is typical of up-to-date expression in economy of space. The cowl is so arranged that it takes up but little room, and the gearshift lever is brought out from beneath the cowl with a bend which carries it directly to the hand of the operator. In place of the ordinary type of hand brake there is a handle which operates on a pull rod through the dash so that the manipulation of the hand brake is rendered exceptionally easy and accessible. A clear aisle is left across the width of the front seat by this arrangement of levers, so that in spite of the reasonable length of wheelbase there is more than a normal amount of room both front and rear.



The powerplant is comprised of a four-cylinder engine, Borg & Beck clutch and a three-speed ball-bearing gearset mounted as a unit. The engine is a 3¼ by 4½ block four, with detachable head carrying the Brush overhead valve gear, which is so designed that adjustments on the valve clearance can be made while the engine is running. An improvement has been incorporated in the valve action by using a full generated rocker pivot.

Aluminum alloy pistons, Lynite, are used. These have a length of 3 9/16 in. and a diameter of 3.24 in., with 3 3/16-in. rings. They are fitted with a 1-in. wristpin, which forms the upper bearing for the 8½-in. drop forged connecting rod, which has a crankpin diameter at the bottom end of 2¼ in., with a 1½-in. length.

The 100-lb. flywheel carries an 8-in. diameter Borg & Beck dry plate clutch. The flywheel itself has an exterior diameter



Olympian chassis with deep frame construction. Note continuous frame bumper at rear

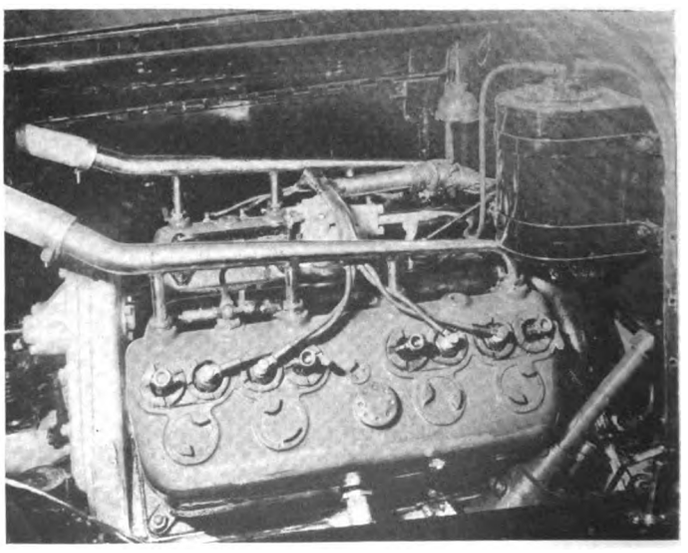
Both sides of the refined Grant powerplant, which is a typical overhead valve six

New Grant roadster, with sloping windshield and rear deck

of 14 in. From this unit the drive is transmitted through a three-speed gearset unit mounted on S.K.F. ball bearings on the main shaft and plain bearings on the countershaft. Both these shafts are 3½ per cent nickel steel. The gear ratios provided are 3 to 1 on low, 1.89 to 1 on intermediate and 1 to 1 on high—the reverse ratio in the box is 3.62 to 1. For final reductions these are all multiplied at the rear axle by 4¾ to 1.

The propeller shaft has two universals and is relieved of torsional stresses by two pressed steel torque arms previously described. The rear axle is a three-quarter floating mounted on Hyatt bearings with a circular type of differential housing to which the tubular shaft housings are bolted on either side.

The body is a five-passenger double cowl streamline type with slanting wind-shield. It is built in the Olympian shops and follows the somewhat angular line now in wide use. It is equipped with an electric light in the rear right hand door for lighting the tonneau and entrance. There is also a two-passenger design of individual lines. The equipment includes a Boyce Moto-Meter, Stewart-Warner speedometer, bumper and a complete set of tools. The price is $1,085.



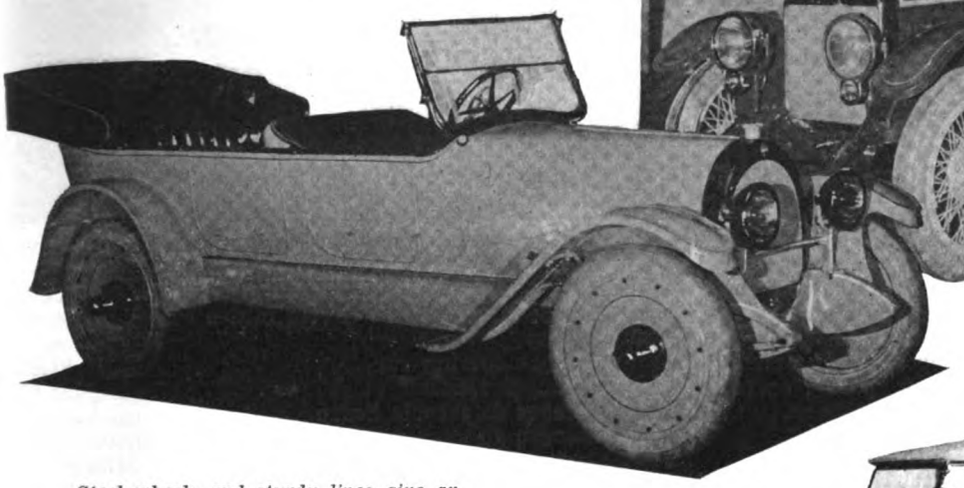
Grant Changes Give Higher Speed Engine

Refinements Made Throughout Body and Chassis Giving Increased Accessibility

IN general design the 1918 model Grant chassis is very much the same sort of machine as its predecessor, but in details there are numerous and important differences. The six-cylinder engine has the same dimensions, 3 in. bore by 4¼ in. stroke (180.3 cu. in.), but changes in design enabling it to run at higher speeds have increased the horsepower. The waterjackets now extend all the way down the cylinders. Filler plates now are placed between the engine crankcase and the frame, thus excluding dust and mud, and to further protect the valve mechanism against excessive wear the valve lifters at the base are covered. The latter are also made lighter than formerly.

A much cleaner appearance of the engine results from the replacement of the old wiring system in which the wires were carried above the cylinders by a new one in which the wires are supported in fiber blocks between the cylinders. This change also reduces the length of the wires and thus improves ignition. The flexible hot air tube formerly used, together with the hot air muff, has been eliminated, the place of these parts being taken by a permanent hot air tube extending from the carbureter over the top of the cylinders directly to a hot air box cast in the exhaust manifold.

Practically all of the bearing surfaces have been increased in size. That portion of the crankcase supporting the bearings has been reinforced, the generator bearing shaft has been increased in length and an oil guard provided to prevent leakage. A V-type fan belt with a simple adjustment is used, and the fan is driven from the crankshaft instead of from the general driveshaft. The lubricating system is entirely new. First the oil pump capacity has been multiplied four times and the oil flow is shown by a gage on the dash instead of by the feed oiler heretofore used. The breather tube and oil filler are now combined and are placed in an



New Peerless L-head engine which takes the place of the former I-head

Both sides of the new Owen-Magnetic overhead valve six made in the shops of the Baker R. & L. Co.

accessible position on the gearcase. The oil strainer has been made larger and may be readily removed for cleaning. Internally the distributing system comprises a tube within the crankcase containing a small opening opposite each connecting-rod and in the gearcase, flooding each bearing surface with oil. Unequal lubrication is rendered more difficult by the use of a new oil trough pan.

Vacuum Tank Attached to Dash

The Sparks-Withington vacuum tank is now attached to the dash instead of to the engine, rendering all parts of the motor head accessible. A Stromberg carbureter is still used, with slight changes.

A two-unit Wagner starting system is used in an improved form. The starting motor is now arranged with a flange bolted to the engine arm, rendering it possible to completely inclose all working parts, including the flywheel, Bendix pinion shaft and starter spring.

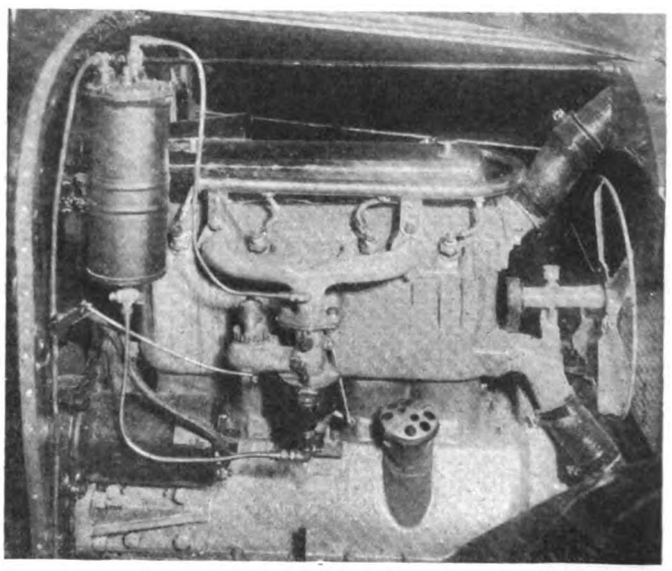
The Remy automatic advance type ignition distributer has been removed from the vertical drive shaft and placed upon a short shaft, eliminating a large number of parts. The spark control mechanism works independently of the timer and the timer cap, so that the timer as a whole remains stationary. This decreases the possibility of loose wires due to the former constant motion of the timer.

The gearbox and clutch are of the same general design, one important change being the provision of a method of lubricating the clutch throw-out bearing. This now receives oil through a hole in the constant mesh pinion gear.

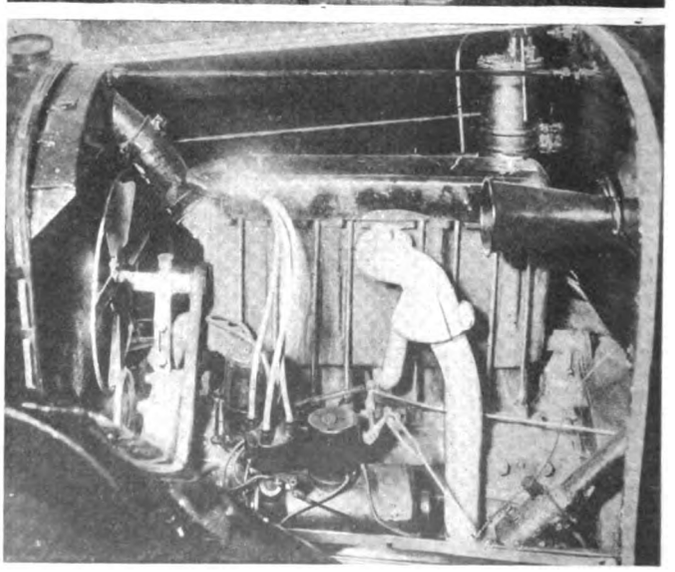
Semi-Steel Castings for Gearbox

Semi-steel castings replace the heavy drop forge arms formerly supporting the gearbox. These are bolted permanently to the engine and support the gearbox. A pressed steel underpan covers the lower half of the flywheel, effecting complete inclosure. A large hand hole however is provided for inspection and adjustment of the clutch and if necessary this steel underpan may be quickly dropped.

Among the other changes are an increase in the throw of the emergency brake lever, permitting more power and action, though the brake construction remains practically the same. The starting switch is now mounted on the gearbox and so made that it requires but a light pressure for operation. A split nut type Jacox steering gear replaces the worm and gear Jacox formerly used, and the horn button is now carried on the top of the steering wheel.



Though the rear axle is similar to the one formerly used the factor of safety is increased by the use of better steel and gears with larger teeth.



Body Dimensions Increased

An increase in the wheelbase to 114 in. has permitted an increase in the body dimensions. The rear springs are 8 in. longer than formerly. An entirely new design of radiator is used, somewhat higher and narrower than the previous one and of reinforced double shell construction permitting ready removal of the core. It is mounted on trunnions permitting it to adjust itself to any weaving of the car frame. Its cooling capacity has been increased and the shell is nickel plated.

In 1918 the Grant will be offered in five bodies at the following prices:

Five-passenger touring car	$1,055
Three-passenger roadster	1,055
Five-passenger detachable Sedan	1,350
Five-passenger all-weather Sedan (Springfield type)	1,595
Three-passenger standard all-weather coupe (Springfield type)	1,575

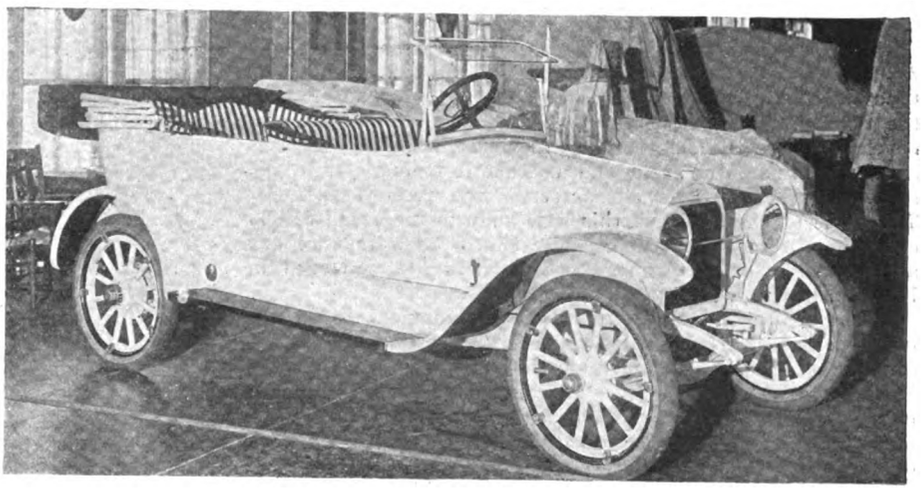
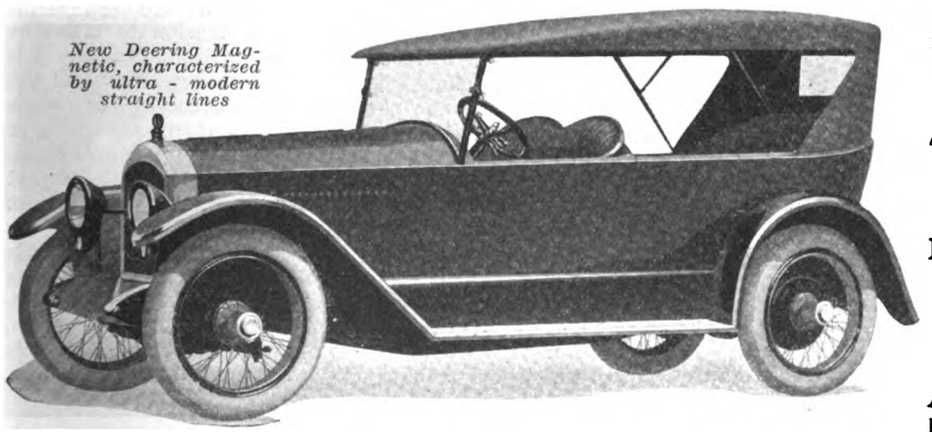
Anderson Has Convertible Sport-Touring

Gives Both Two- and Five-Passenger Bodies



THE Anderson Motor Company of Rock Hill, S. C., has a new car at the show in the shape of a convertible sport model which may be transformed from a roadster to a five-passenger model. The rear compartment can be closed over, thus forming a rear-deck roadster, or when it is opened it uncovers a rear compartment which allows of three additional passengers. This convertible model comes in two styles, one with divided front seats and the other with a solid front seat and entrance to the rear compartment through a door at the rear on the right side of the car. The convertible feature of the car is patented by the Anderson company.

The convertible model with the rear door is a larger type than the one with the divided front seat and is known as the De Luxe. The engine is larger in this model, being the new Continental 9 N, 3½ by 5¼ in., six-cylinder type. The other features of the car are similar to the standard Anderson product. The clutch is a Borg & Beck, the transmission is a three-speed selective and the rear axle a Columbia.



One of the interesting features of the De Luxe convertible is the method of top adjustment for the roadster. There are two pillars which are concealed in the body just behind the front compartment and a curtain top which pulls over the front compartment on a spring roller. The De Luxe convertible sells for $1,925, the convertible sport $1,465, four-passenger $1,465 and the sedan $2,165.

Templar Exhibits Its Product for First Time

Has Four - Cylinder Overhead Valve Unit of 197 Cu. In. Displacement

A NEW car with a new design of overhead valve engine is being exhibited by the Templar Motors Corp., Cleveland. The car is an assembled product with the exception of the engine, which has been designed in the Templar shops and will be built by the company itself. The engine is a four-cylinder product of 197 cu. in. piston displacement and is claimed to develop 43 hp. at 2200 r.p.m.

The powerplant is a detachable head unit with 3⅜ by 5½-in. cylinder dimensions. The valve action is a rocker arm type with the rockers covered by an aluminum housing. The vertical push rods operate in a hollow space which is so arranged that there is a continuous oil vapor from the crankcase surrounding the valve action and keeping the parts lubricated. The valve rocker shaft is part of the pressure oil feed system.

Digitized by Google

The clutch is a Borg & Beck single dry plate with multiplying levers and ball bearing release. The drive is taken through a three-speed gearbox operating on New Departure ball bearings to a hollow propeller shaft with two Schwitzer universals and a semi-floating American Ball-Bearing Co. rear axle. The springs are semi-elliptic front and rear, the length being 54 in. in the rear and the bushings are Nigrum oil-less type. The tires are 32 by 4 Goodyear Cord, straight side. The five-passenger and the four-passenger sell for $1,985, the four-passenger for $2,155, and the two-passenger touring-roadster for $2,255.

Owen-Magnetic Refined with New Overhead Valve Engine

Chassis Is 6 In. Longer, Now 142-In. Wheelbase —Improved Body and Better Equipment —Price Raised $1,000

A NEW Owen-Magnetic is on exhibition for the first time. In body work it is probably one of the most distinctive types at the exhibition and carries out to a marked degree the tendency toward the beveled edge. The hood lines are beveled, as are the side rails of the body, and this effect is carried around to the rear end, so that it finishes off in the same angular style as characterizes the rest of the car. The price of the car with this new body is increased $1,000 over the former price, being now $5,475 as a touring car and $6,500 as a limousine. These prices are delivered in New York and include the war tax.

Mechanically the most important development is in the use of a new overhead valve engine. There is also a better control, which more uniformly graduates the intermediate steps in speed control. The new control apparatus also permits of a better braking action by allowing the current of the motor, acting as a generator, to increase the field strength of the electrical driving unit, thereby giving an increased drag on the armature for more severe braking.

Car 6 In. Longer

The new car is now 6 in. longer in wheelbase, being 142 in., as compared with 136 last year. This is made necessary by the rearranged body and larger engine. The new engine is a 4 by 5½ overhead valve six, with the cylinders cast in two blocks of three, the overhead valve construction being carried on a single detachable head which fits both cylinder blocks. The engine is capable of delivering 80 hp. on the brake, according to the claims of the makers, and is manufactured specially for the Owen-Magnetic cars in the Baker R. & L. shop.

Both the upper and lower halves of the crankcase are aluminum castings. The upper half is a ribbed structure stiffened to support the main bearing and to carry the crankshaft load. The latter not only must perform the usual duties but must also support the revolving member of the magnetic clutch, forming a part of the transmission, which acts in place of the conventional flywheel. The pistons are ground and lapped into the cylinder and drive through drop-forged, oval-section connecting rods.

The camshaft and the water pump and magneto shaft are driven from the crankshaft by means of a timing set composed of three helical gears inclosed by the aluminum cover. The valves are tungsten steel, 1⅞ in. in diameter, and are used in connection with the overhead system carried in the detachable cylinder head. They are operated by drop-forged rocker arms and push rods entirely inclosed by cover plates. These rods can be adjusted by removing the single aluminum top cover running the full length of the detachable head.

The exhaust from the engine is led by the manifold to the forward end and the exhaust pipe curves down from that point below the body, thus keeping the heat away from the front compartment. The intake and exhaust manifolds are both on the left side, and the intake passages are arranged so that the single connection to the carbureter is cast integrally with the exhaust manifold and passes through it. This gives a highly preheated mixture and aids in the vaporization of the fuel.

Gasoline is fed by the Stewart vacuum system, and ignition is by a Bosch high-tension magneto. Lubrication is by pressure feed, with the gear pump supplying the lubricant under a head of from 20 to 30 lb. at normal running. The pressure is proportional to the power requirement, and the oil under pressure is taken directly to the camshaft rocker arm bearings and timing gears besides the bearings directly concerned with the operation of the crankshaft. Cooling is by centrifugal pump, the pump being on the same shaft as the magneto. A Sylphon thermostat is located at the upper tank of the radiator, checking the flow of the cooling liquid through the radiator by means of a bypass until the proper running temperature has been reached.

There is no alteration in the electrical system other than in the control unit mentioned. The chassis frame has been strengthened to support the longer wheelbase and is now 8 in. deep, of pressed steel channel section, provided with many stiffening cross-members and gussets. Although the wheelbase is 142 in., the turning radius is but 24 ft. The rear springs are now 61 in. long and are underslung. The standard rim equipment is Firestone straight side, and the tires are 35 by 5 in. cord, with ribbed front and non-skid rear.

Crow-Elkhart Building Own Overhead Valve Engine

Former Type Supplanted by I-Head Engine and Unit Powerplant Replaces Axle Unit

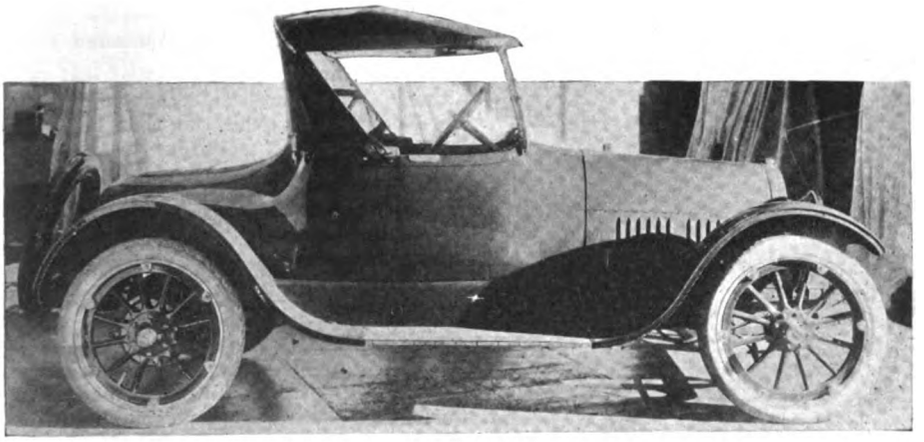
CROW-ELKHART is showing for the first time its revised car employing its own new valve-in-head engine. The engine is a rocker arm type, four-cylinder 3½ by 5, with a counterbalanced crankshaft having the counterweights electrically welded into place. The new car contains several changes in practice as compared with previous Crow-Elkharts. In the former L-head engine a two-bearing crankshaft was used, whereas in the new type there is an additional bearing.

Oiling is now by splash pressure, cooling by thermo-syphon and in place of the three-quarter elliptic springs, semi-elliptics are employed with a frame extension to take the place of the quarter which has been removed. Another big change is the abandonment of the rear axle gearbox and the substitution of the unit powerplant. In place of the clutch formerly made by the Crow-Elkhart company the Borg & Beck dry disk type is being used and in place of a cowl gasoline tank the tank has been moved to the rear and Stewart vacuum feed employed. Other detail changes have also been put into effect such as a sloping windshield in place of the vertical, a curved cowl, lower seats in the front compartment and twelve varieties of color offered as stock. The five-passenger touring car sells for $935, the De Luxe touring at $995, De Luxe roadster, $995, coupe, $1,295 and sedan, $1,395. For $100 extra a complete set of Houk wire wheels is supplied. The upholstery is either in Spanish brown or black long grain leatherette.

Moore Car Is New Assembled Unit

Employs Standard Parts Mounted on a 106-In. Chassis

THE Moore Motor Vehicle Co. of Danville, Ill., has on exhibition a car on a 106-in. wheelbase, selling for $695. It is an assembled product with a Golden-Belknap & Swartz, four-cylinder, L-head engine, disk in oil clutch, Grant-Lees three-speed gearbox, Peru floating rear axle with Hotchkiss drive and 30 by 3½ tires. The car is furnished in either black or brewster green.



In equipment the Dyneto lighting and starting is furnished in connection with an 80-ampere Willard storage battery. Ignition is provided by Dixie magneto. The car is mounted on cantilever springs.

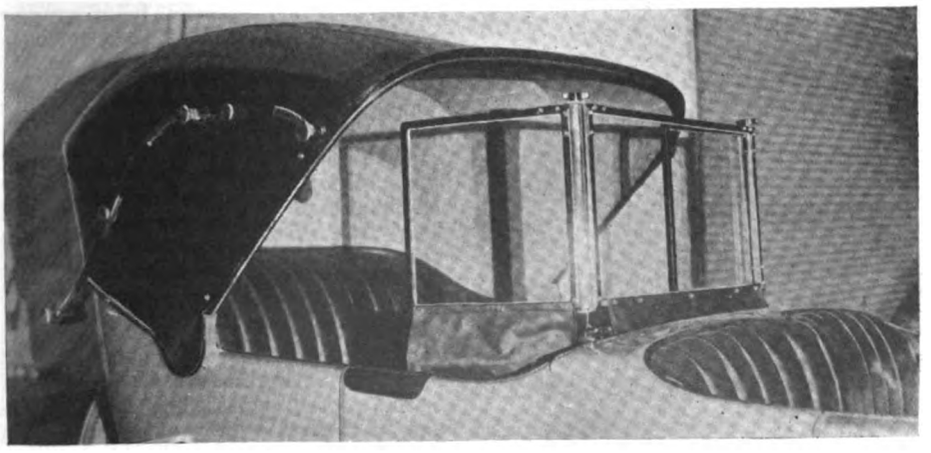
Stock Bodies Uniformly of Good Design

Angular Lines with Flat Sides and Sharp Corners Gracefully Handled—Beveled Edge Type Prominent



By George J. Mercer

Buick runabout, showing the gypsy quarter

Scripps-Booth runabout, with straight line extending around rear

Mercer, showing victoria top and tonneau windshield

THERE are some real new bodies at the show. These designs are the products of the last few months and represent the latest practice.

Innovations in design are not brought out solely to have something new, but are set in motion generally to meet a real need. Style is arbitrary and carries along until the sameness becomes irksome or is superseded for practical reasons. Not always does the change meet the requirements sought. It is brought into existence to remedy or meet a want, and with different minds working along the objective, different results are obtained until finally the blend of ideas will produce a permanent design that becomes standard.

The opportunity for change is greater in open bodies than in closed, and the runabouts are the most prolific breeders of innovations and consequently they are less standard than other types. These bodies are the most cheaply made and may be experimented with at less financial risk. This is amply borne out by show types, as the following studies will show.

What Drawings Indicate

Figs. 9 and 6 are criticisms of details that mar the design out of proportion to their actual demerit. Fig. 9 is a case of having the radiator too narrow to blend with the body side line. Formerly the radiator was governed solely in size by the requirements of its cooling, but with the flush sided body the body lines converge at this point, and if the width is as narrow as the illustration the converging lines give the appearance of a pencil point, because the middle width of the body is established by the seat room.

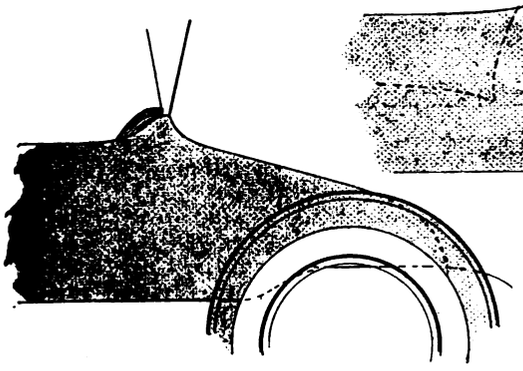


Fig. 6 is another thing that destroys the good general appearance. The guard may be nearly right in every way, but if the space between wheel and guard at rear is more, proportionately, than at the front and top of wheel, it gives a distorted appearance. The guard should circle the wheel about as shown in Fig. 7. It is not absolutely necessary that the lower end curve the reverse as shown, but a guard with this shape certainly looks a better balanced one.

Of the runabouts at the show, the majority were those having a stern or hamper like the photographs of the Buick and others. Usually this hamper

Digitized by Google

Good and Bad Points of Body Design

Fig. 1

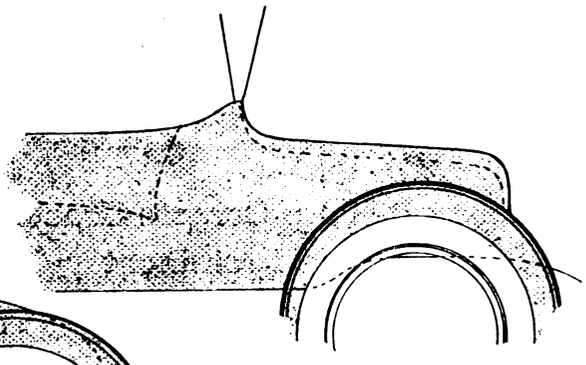

Fig. 2

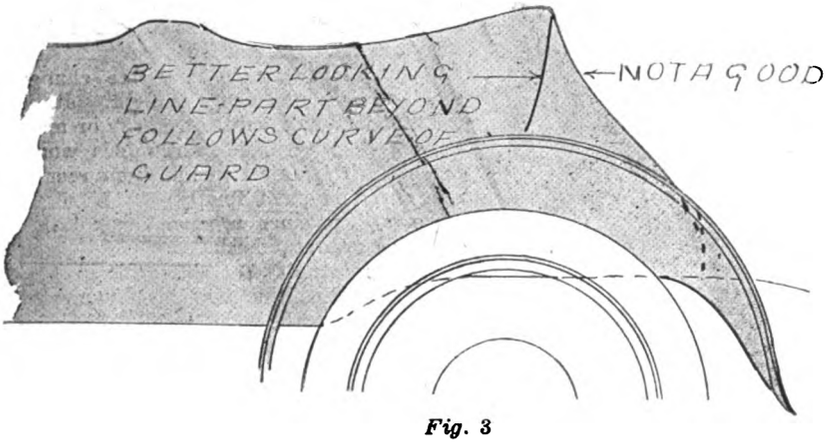

Fig. 3

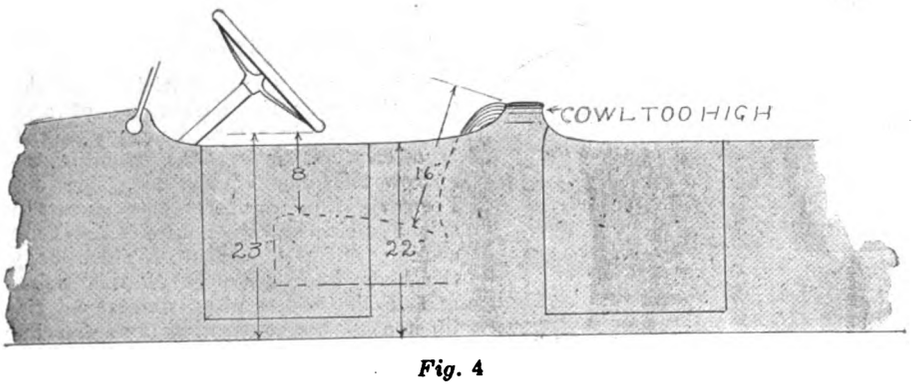

Fig. 4

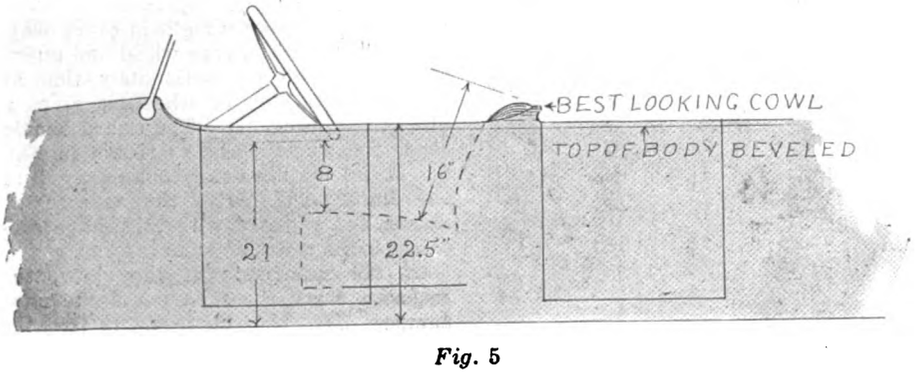

Fig. 5

contains a concealed seat. The making of a good-looking hamper has been a trouble to designers for years. Every possible shape has been tried, and the illustrations, Figs. 1 and 2, show the good and bad of it. The good is when the top deck is nearly horizontal, as in Fig. 2, while the shape as illustrated in Fig. 1 lacks definiteness as well as good lines. The great majority were of the better shape.

Fig. 3 is another illustration in which the good and poor lines are shown together. This hamper is shorter on account of being adapted from a clover leaf runabout. In this, as in the previous illustrations, the poor line is when same has an indefinite character.

Close-Coupled Body in Ascendency

In continuation of the clover leaf runabout, it was noticeable that there were less of these on exhibition than last year. At that time it looked as if this body type had made a permanent place for itself, but in the desire to make them compact, proper space to seat four people was never allowed. The result has been that the sport close-coupled touring body has begun to supersede it. This latter has the advantage of the four doors, it is better looking, the front seats are divided, and it has comfortable seats for four. But on some models the sides are too low and the manufacturers will cripple its coming popularity unless the body sides are high enough to come sensibly above the top of the cushion. Photographs of this body design show the Hudson and Cadillac. One of these shows the low and the other the moderately high side.

A good way to detect the proper height for the side is to compare on the side line the height of the cowl above the body side. If the disparity is excessive according to general practice, the seat cushion must be very close to the floor or the sides will not give adequate protection.

Essentials in Touring Bodies

In connection with the subject of the height of the sides of touring bodies, Figs. 4 and 5 will assist in answering the question that every car owner asks —why a certain recognized body looks better on one chassis than another. What we consider as essential in a touring body is low sides and an inconspicuous top to the driving seat. The second cowl, as shown on Fig. 4, is doomed. In its place has come the combination of the second cowl and the older seat back unified as shown on Fig. 5. To look well it should not come much above the side body line, and the dimensions given on these two illustrations show that in order to end right the starting point or position of the steering wheel is all powerful in getting results.

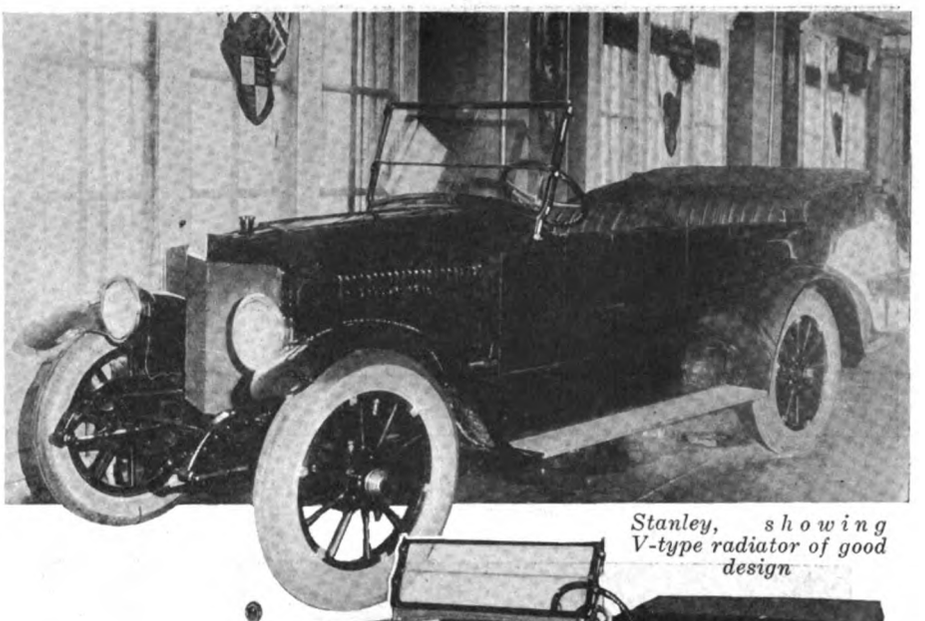
The second cowl, as shown on Fig. 5, is in most cases the continuation of the bevel edge of the body top. This bevel edge is rapidly superseding the rounded edge, as it gives a lower side appearance and a more distinct line of demarcation; also it makes it possible to continue the

Digitized by Google

side line straight through from the hood, when the latter is high enough to start. Several of the photos illustrate this.

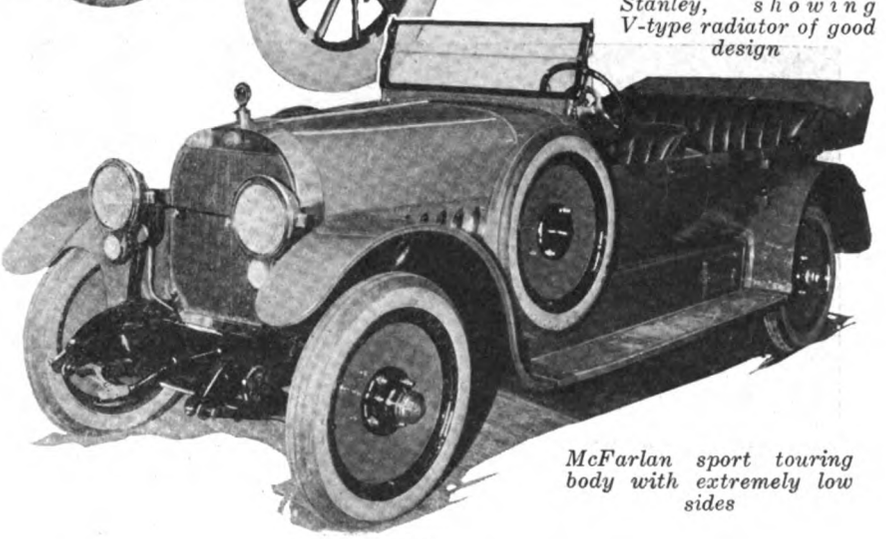
Fig. 10 shows how the bevel edge should finish at the hood cowl. Along the body edge the width of the bevel is never less than 1½ in., but if this is continued around it looks too heavy; whereas if lightened, as illustrated, the appearance is wonderfully improved.

While the height of the driving seat back has been minimized to the extreme, the height of the rear seat is retained at 19 in. or over above the cushion top. This high back is always concealed when the top is down, and when it is up the gypsy quarter, which has become increasingly popular this season, will cover all above the body line, which is kept low or nearly horizontal to obtain the straight line through from the front to rear. Several of the photos illustrate these two points.



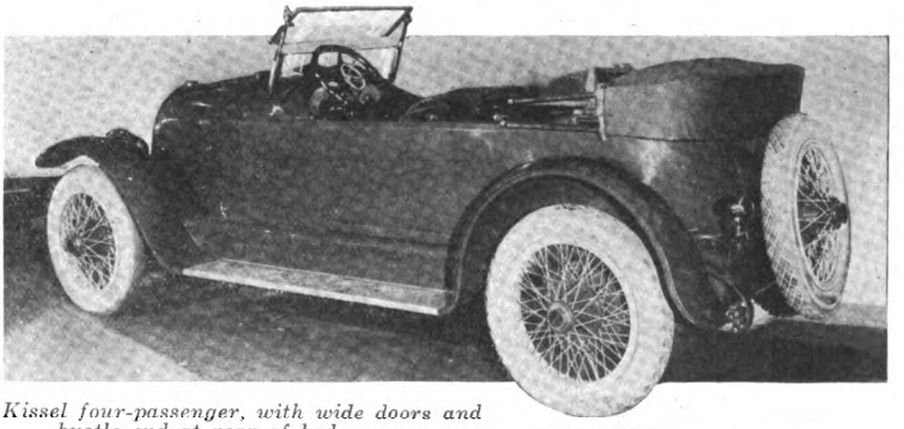
Use of Straight Lines

Fig. 8 illustrates how the straight line can be used even if the hood is slightly low. To continue straight back, this line has from all time been horizontal, but since the custom has obtained of raising the top line of the hood, the hinge line can be raised and still appear horizontal. In fact, on some cars where the frame sets lower than customary at the rear, this hood hinge line has the appearance of dropping toward the rear, and viewed from certain angles seems to carry the impression to the frame and gives the look of a sag at the dash.



The closed bodies, while not so numerous as formerly, had a better or lighter appearance than at any other show. Figs. 11 and 12 are two illustrations which show how this is accomplished. Each illustration shows the belt molding and the roof. One, that on Fig. 11, shows the roof line straight and the side edges accentuated, the height of the crown being invisible beyond. The part that shows is blackened and the line of the roof center which is invisible from the ground is indicated by a single line. On Fig. 12 the roof is rounded to the center and the total thickness is always apparent. Rounded edges will on certain parts of the body give the impression of lightness, but on a roof it always adds thickness to the looks.

Belt Molding



There is another point that is shown in the reverse relation on most of the bodies. The belt molding was shown as Fig. 11, but on a few they were as Fig. 12. The excessively heavy belt is only excusable when a makeshift proposition like a demountable top is put on a touring body. In this case, framing sufficient for the purpose must be added, and without a chance to conceal any of it. But with a properly built closed body there is no reason to show such heavy construction. It serves no useful purpose and detracts from the clean-cut look that might be otherwise obtained as shown in Fig. 11.

Owen-Magnetic, the only cubist body at the show

There were more town car bodies than at any time in the past few years. They were of the brougham-limousine and cabriolet types, and some of the former had square rear corners. In fact, all the town car bodies had the regulation custom-built body appearance.

The windshield height on a town car body varies so much that Fig. 13 is introduced to make clear the needs requisite. The dimensions given are the height for headroom and for vision, and provided these are fairly well proportioned, the top curtain should come as far down as possible so as not to have a tall shield.

The various photographs illustrate as well as the sketches the points accentuated, and in addition some others, like the increased use of the Victoria top. One shows in conjunction with the top a tonneau shield. Good shaped guards are the rule, the moderate crown being the most common. Good guards make a lot toward the appearance of a car; especially is this noticeable when the front guard in addition to being well shaped is of generous length before attaching to the runningboard; also the slight outward curve at the bottom of the rear is an advantage.

The slanting windshield was the rule. There were few cowl lamps. Many of the touring bodies had a sensible bevel top body edge and a moderate height to the back of the driving seat. These bodies were of metal and showed good workmanship. The total absence of molding was another feature, and the doors had either the overlap panel or were flush, and there seems to be a reverse move toward the outside door handles. This is probably due to the trouble of locating the inside handle from the outside, as well as the objection that many have to the leather pad neces-

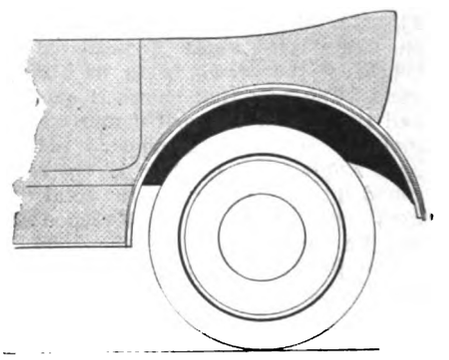

Fig. 6

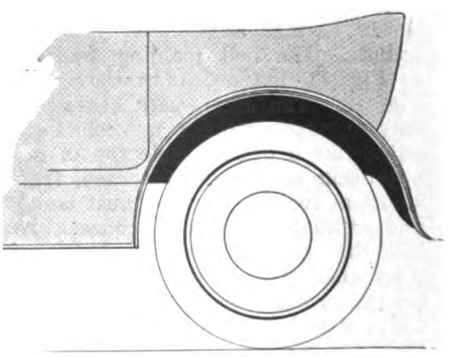

Fig. 7

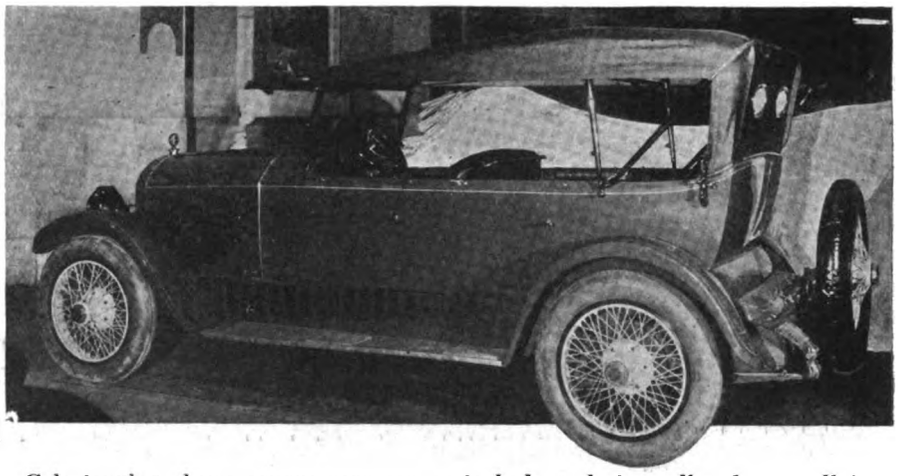
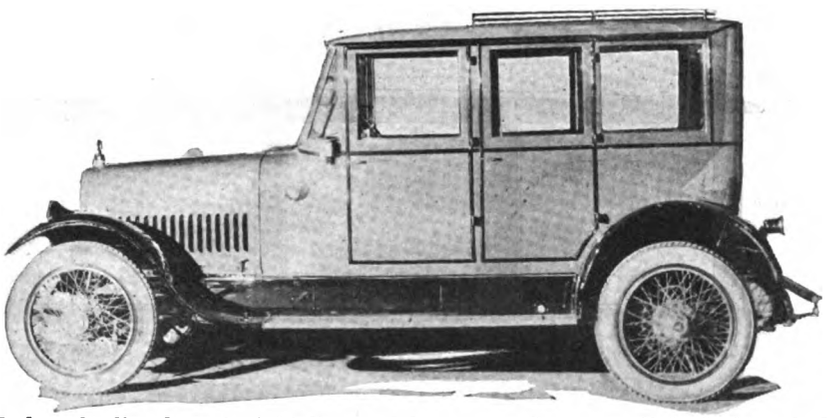
Digitized by Google

sary for closing the door when there is no handle outside.



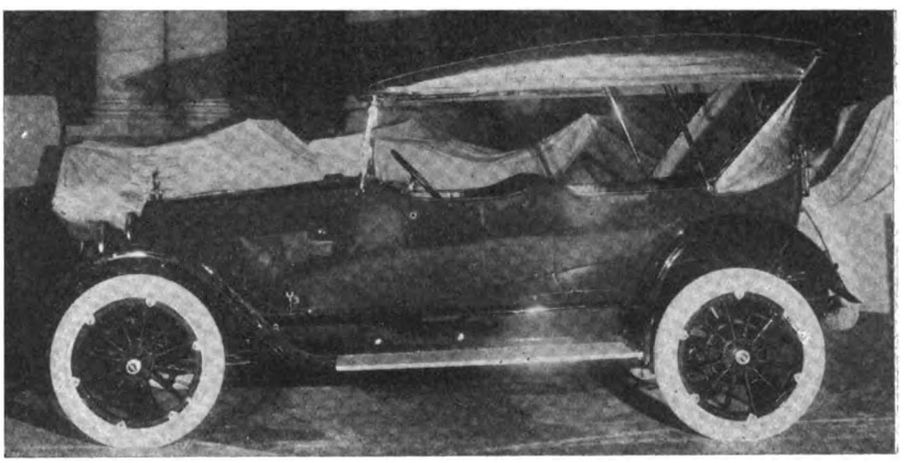
At the Astor salon there were bodies with the handle at the top of the door. Wheels or tires were placed with a very few exceptions at the rear of the car. This is good practice as it adds traction where needed. Both wire and disk wheels were common; wire wheels particularly were used with all the different kinds of bodies.

The trimming design on these touring and runabout bodies was almost exclusively the plain pleat. Leather was used principally. Some had imitation leather and a few had Spanish leather, while a few used a plush cord. The extra seats were of the floor flush type, and a lavish display of paint combinations was to be seen. Some were not good by reason of the shade or the combinations. The blue that looked almost green in the electric light was a good color, especially when relieved with white or yellow wire wheels. The bronze green, with red wheels, was good, as were many of the grays, coffee color and brown and yellow. Many of the light shades looked sickly because of the combination. The stripe line around the body below the top was a failure in most all cases. A double yellow line on a green body and a red line on a bronze green were the best illustrations. Some had the line too heavy, and altogether it seems that the putting on of this stripe is a delicate task.



The closed bodies were equal with the open in presenting color schemes, with this advantage, that the combinations were more uniformly successful. There were the usual number of black bodies, but colors were plentifully sprinkled about. The trimming design on closed bodies was generally the plain pleat. Some had the plain design, and there were others that had the plain effect divided. The material was more somber in design than formerly. The medium light cloths were most popular. These were used without marking for the body of the job and the headlining and a striped design for the seat and back.

In some cases the plain cloth was used throughout, and also the figured material was used for the lower part up to the waist line.



The appointments were gun metal or gold or dull silver. The toilet cases were elaborate in design. There was a

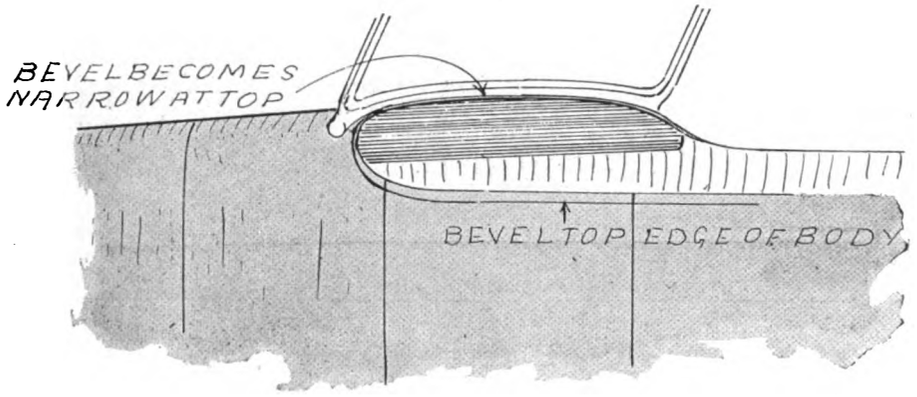
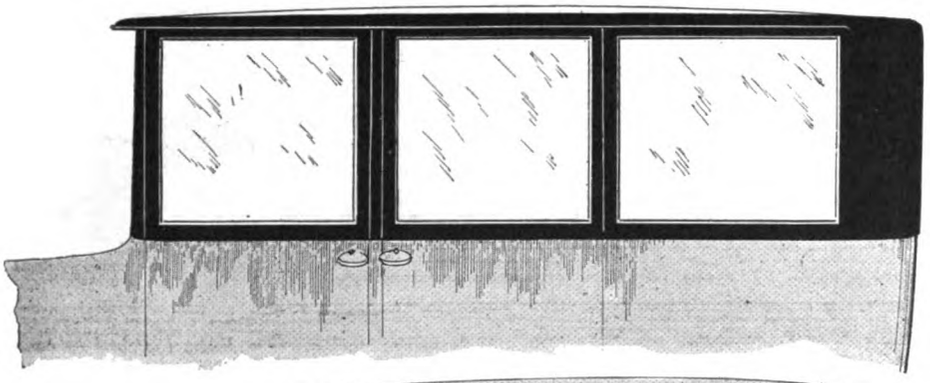
Modern Body Lines Analyzed





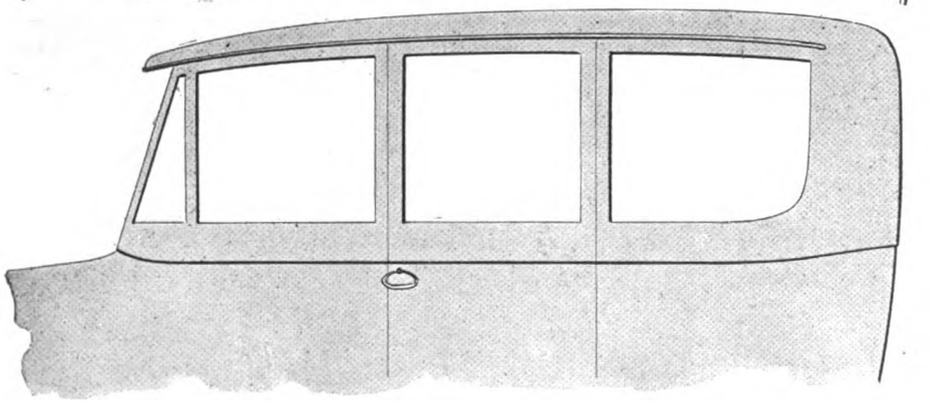


Fig. 10

Above—Fig. 11. *Below—Fig.* 12

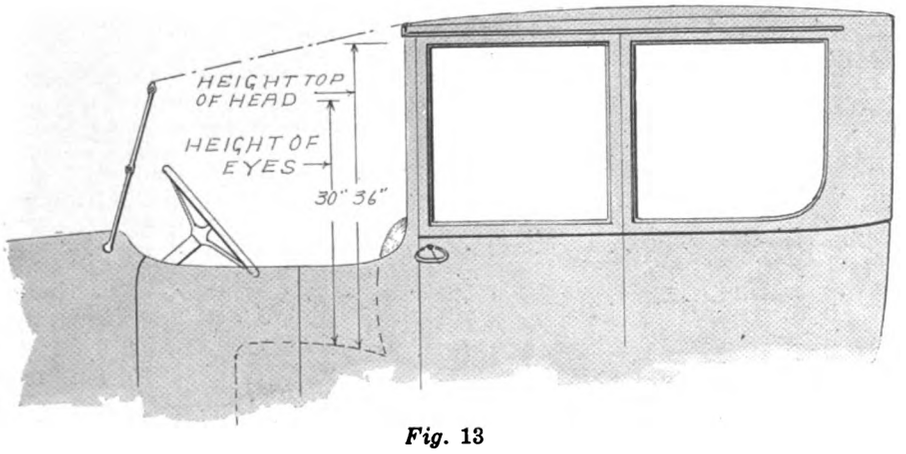

Fig. 13

total absence of interior inlaid woodwork, and there were several bodies without dome lights, the corner reading lamps set in flush but not concealed being the only light to be obtained. There were both the telephone and dictograph used and the pull-to handles were of good size, of metal and sensible for use.

As before stated, the closed bodies had a lighter look than in former years; there was a total absence of the large round roofed cumbersome bodies formerly so common. The berlines were of the divided sedan order. Sedans seem to be the popular body and the convertible with the flapper door were similar to those of last year.

Altogether the exhibit looked good because it was good. Designers of bodies that did not possess the merit that they should, had a splendid chance to see their mistakes, because there were good body designs of every type that were well worth using for models.

Texas Has 194,740 Registered Vehicles

AUSTIN, TEX., Jan. 5—During the first five and one-half months, up to Jan. 1, 1918, that the State Highway Commission was in existence there were registered a total of 194,740 motor vehicles, including automobiles and motor trucks, and 3579 motorcycles. The number of dealers in the State is 3094. Licenses were issued to 12,696 chauffeurs, of whom about 25 per cent are in San Antonio. In the registration of motor vehicles there is no separation of automobiles and motor trucks. Included in the motor trucks are those owned and operated by the United States Army and other departments of the Federal Government, but no registration fee is charged for these. It is difficult to give anything like a reliable estimate of the total number of motor trucks in the State but there are probably ten thousand or more in operation. It is known that many automobiles and other motor vehicles have escaped the registration law. It is believed that if all were registered the total number would be close to 225,000. According to unofficial reports made by the county clerks of the different counties several months ago there were at that time more than 225,000 automobiles in Texas.

Asks Cities to Eliminate Snow Troubles

WASHINGTON, Jan. 6—Because the severe snowstorms of the last two weeks have greatly affected the movement of war supplies and tied up city traffic to an alarming degree, the Highways Transport Committee is urging authorities in all cities to keep the streets on which freight is hauled as free as possible. This will facilitate the movement of products and relieve terminal congestion. Merchants and manufacturers in these sections have been asked to cooperate with city authorities by loaning men and wagons or motor trucks during such emergencies. It is also imperative that main arteries of highway travel between industrial centers be kept free of snow so as to permit traffic.

British Aviation Engine Inspection

Part I

1—Chart scheme of complete system in use

2—Best methods of employing women in work

3—Routine for rejection by government men

4—Plan of using approved firms is favored

5—Advantages of inspection to companies

By Lieut.-Col. R. K. Bagnall-Wild

EDITOR'S NOTE—*The British Government is reputed to have the most rigid inspection of any. Lieut.-Col. R. K. Bagnall-Wild, who has charge of the inspection of British aeronautical engines, is also president of the British Institution of Automobile Engineers for* 1918. *In his opening address to that body he analyzed the reasons for and methods employed in government inspection. While the system may be criticised, it is thorough and worthy of study.*

IN considering inspection we have first to ask the question, Why inspect? An inspecting staff is expensive and is usually classified as non-productive labor; therefore, it is obvious that the greatest possible care must be exercised in restraining those responsible for inspection from unduly inflating their staff beyond the minimum requirement.

It will, perhaps, help to realize why inspection is necessary if the various classes of men employed in production are compared. Omitting laborers, there are in average engineering works a majority of workers, both male and female, who, although graded as mechanics, are practically repetition workers. It is not necessary for them to have the training and the brain knowledge of the higher grade engineer. The further we progress with the introduction of automatic machines and a general system of repetition work, the more shall we be able to use less highly skilled labor. A certain proportion of the employees in an engineering firm must necessarily have skilled knowledge in tool setting, gauge making and the like, but they will not necessarily have general engineering knowledge. Even the more highly skilled men, who are employed as foremen over these various classes of labor, only require knowledge in their particular branch, from a production point of view. But from an educational point of view, all these grades, from the lowest to the highest, must naturally, if they wish to progress, obtain the knowledge necessary for promotion, and it is our duty to see that they do progress. This institution is in a position to grant unique facilities for improvement and advancement.

Start on Drawing

There is yet another branch which must be considered before the necessity for inspection can be clearly realized, and that is the design and drawing room. The engineer puts forward a design, the drawing room works it out in detail. Those drawings should be reproduced as shop drawings, showing the various processes for each part and clearly laying down the limits which are to be worked to and the material from which the parts are to be made. Starting with materials—it cannot be expected that the producer, *i.e.*, the mechanic, should have the knowledge required to determine whether that material is in accordance with the specification or not, and further, it is impossible for him, should the material be slightly above or below the limits of the specification, to determine whether it is safe to employ that material for the purpose for which it is intended.

The designer may justly be entitled to expect that a finished article is in accordance with his wishes, otherwise he could hardly be responsible for its correct functioning. Some department must, therefore, exist to take this responsibility, and an inspection branch for this purpose is essential. It is obvious that if incorrect material is allowed to go into the machine shop it will result in either scrap in the machine shop, or scrap when the finished article is put on test, or subsequent early failure. Undue scrapping in the machine shop upsets the steady flow of production—failure on test is excessively costly; the failure of one part may often lead to the scrapping of a considerable portion of the whole. For example, steel bar must be inspected to see that it is in accordance with the specification. Say it is nickel chrome steel bar, it might not be economical to machine it in its final hard heat-treated condition; it must, therefore, be received in the normalized state. Inspection alone will determine whether the heat treatment given for the finished article will produce the physical properties required by the designer. The bar must also be tested to show that when heat-treated the desired physical properties can be obtained.

Machine-Shop Inspection

Looking at inspection from the machine shop point of view, the workman desires output, because it gives him more money; the foreman desires output, for therein lies his chance of promotion; the production manager is obviously, if I may say so, the enemy of the designer, it is only human nature that this should be so. The directors and shareholders of a company must, therefore, protect themselves from bad workmanship, the reputation of the firm must be upheld and the finished article must be as good as is possible, having due regard to prime cost. Inspection alone will insure this. This need only be selective inspection in many cases, the main point being that a check must be kept on shop gages, tool setting (especially with automatics), etc., and any departure from drawings at once located, checked and nipped in the bud. If, for example, errors are allowed to creep in in the earlier processes, when there are ten or twelve operations, perhaps, in making one piece, it is quite clear that the cost and time of the remaining processes will be saved if the error

Digitized by Google

is checked in the earlier stages; consequently inspection is needed between each operation.

I could give a whole number of cases where I have found firms completing ten or twelve operations, and then having to scrap the part because the first operation was wrong, simply because the firm had no process of inspection of its own.

Spare Parts

Again, inspection of a finished part is absolutely essential prior to assembly of all the parts into the whole. A well-organized shop with a proper system of inspection results in a saving of time and money in erection. In many cases where the viewing of the output of the machine shop is slack, or is lacking, erection practically becomes "hand-fitting," interchangeability is entirely lost and spare parts impossible to fit. In other words, no two articles are alike. An organization, therefore, is required on the following lines: A small inspection staff to deal with all goods in the receiving or inward store (nothing being allowed to go into the machine shop unless bearing the stamp of that Inspection branch), and a complete system of process inspection in the machine shop and a view room between the machine shop and what may be called the erection or main store, so that nothing can go out of the main store to the erection shop unless it has been checked, stamped and certified as reasonably likely to be capable of being built into the whole without undue fitting and, also, to be able to correctly fulfil its functions.

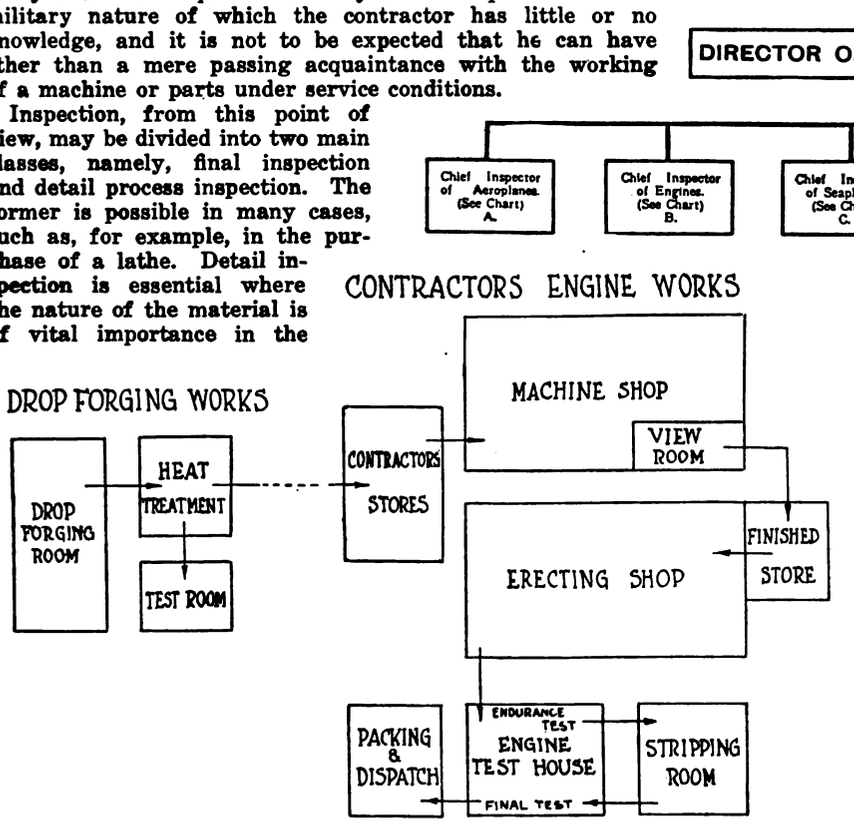
Another small inspection staff is desirable in the despatch store to see that packing cases are adequate and correctly built to design, if any, and also to see that bright parts and so on are properly greased and every care taken that the goods are packed in such a manner as to be likely to arrive safely at their destination.

Turning now to the purchaser. The average purchaser is content to take a firm's name as a guarantee that the goods supplied are in accordance with the order. The purchaser usually protects himself by seeing that the articles are externally correct and function reasonably in accordance with his requirements.

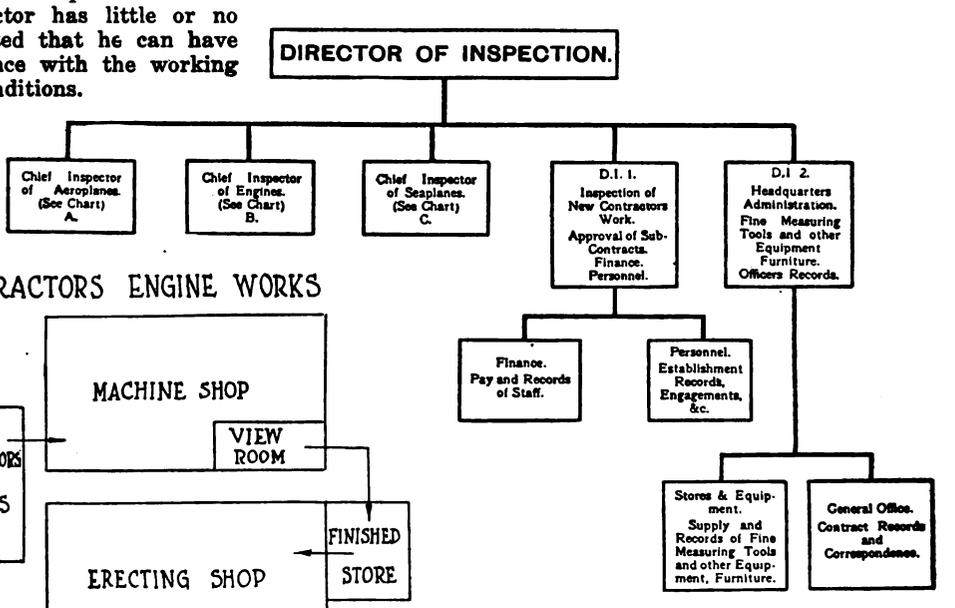
Government departments go a great deal further than this. In the first place they are responsible for public funds and have to insure that value is obtained for money expended. In many cases the requirements may be of a special naval or military nature of which the contractor has little or no knowledge, and it is not to be expected that he can have other than a mere passing acquaintance with the working of a machine or parts under service conditions.

Inspection, from this point of view, may be divided into two main classes, namely, final inspection and detail process inspection. The former is possible in many cases, such as, for example, in the purchase of a lathe. Detail inspection is essential where the nature of the material is of vital importance in the functioning of the whole, as occurs where the factor of safety is low.

Inspecting Material



Detailed inspection during manufacture should not be necessary where a firm has a good view room of its own. In this case material must be inspected on or before entering the plant: steel should be inspected where it is made, namely, at the steelmakers' works or at the rolling mills. Any faulty material is then at once thrown out, or should be, and the steelmaker has an opportunity of tracing the trouble to its source. Freight to and from the steelmakers' and contractors' works is saved; in fact a double journey is obviated, as faulty material would probably be returned to the maker by the contractor. The inspector should exercise general supervision to insure that no parts are made from material which has not been so passed in the plant.



The next place where the inspection department picks up the thread is where parts have left the machine shop, and here again the amount of inspection necessary entirely depends upon the firm. As a typical example we may take the case of a good manufacturer who is, say, erecting 80 per cent of his products into finished machines and sending away the remaining 20 per cent as spares; it would probably only be necessary for the government inspector to inspect the spares, the machine itself being inspected after erection. If a running test is involved, this is carried out under the supervision of an inspector and careful examination is made upon conclusion to see that no parts are unduly worn or fail in their action.

Fig. 1 is a diagrammatic representation of an ideal inspection arrangement in connection with the production of crankshafts.

Departmental Co-operation

In considering the question as a whole, I must emphasize the necessity for a dovetailing of, and co-operation between, the various departments. In the first place the drawing room and inspection branch must come to a mutual agreement before the issue of drawings to the shops. Experience has shown that drawings as produced are very seldom clear or suited for commercial production. In some cases they even lack limits entirely and, where limits are included, there is a tendency in most drawing rooms to unduly tighten down

LEFT—*Fig.* 1. ABOVE—*Fig.* 2

Digitized by Google

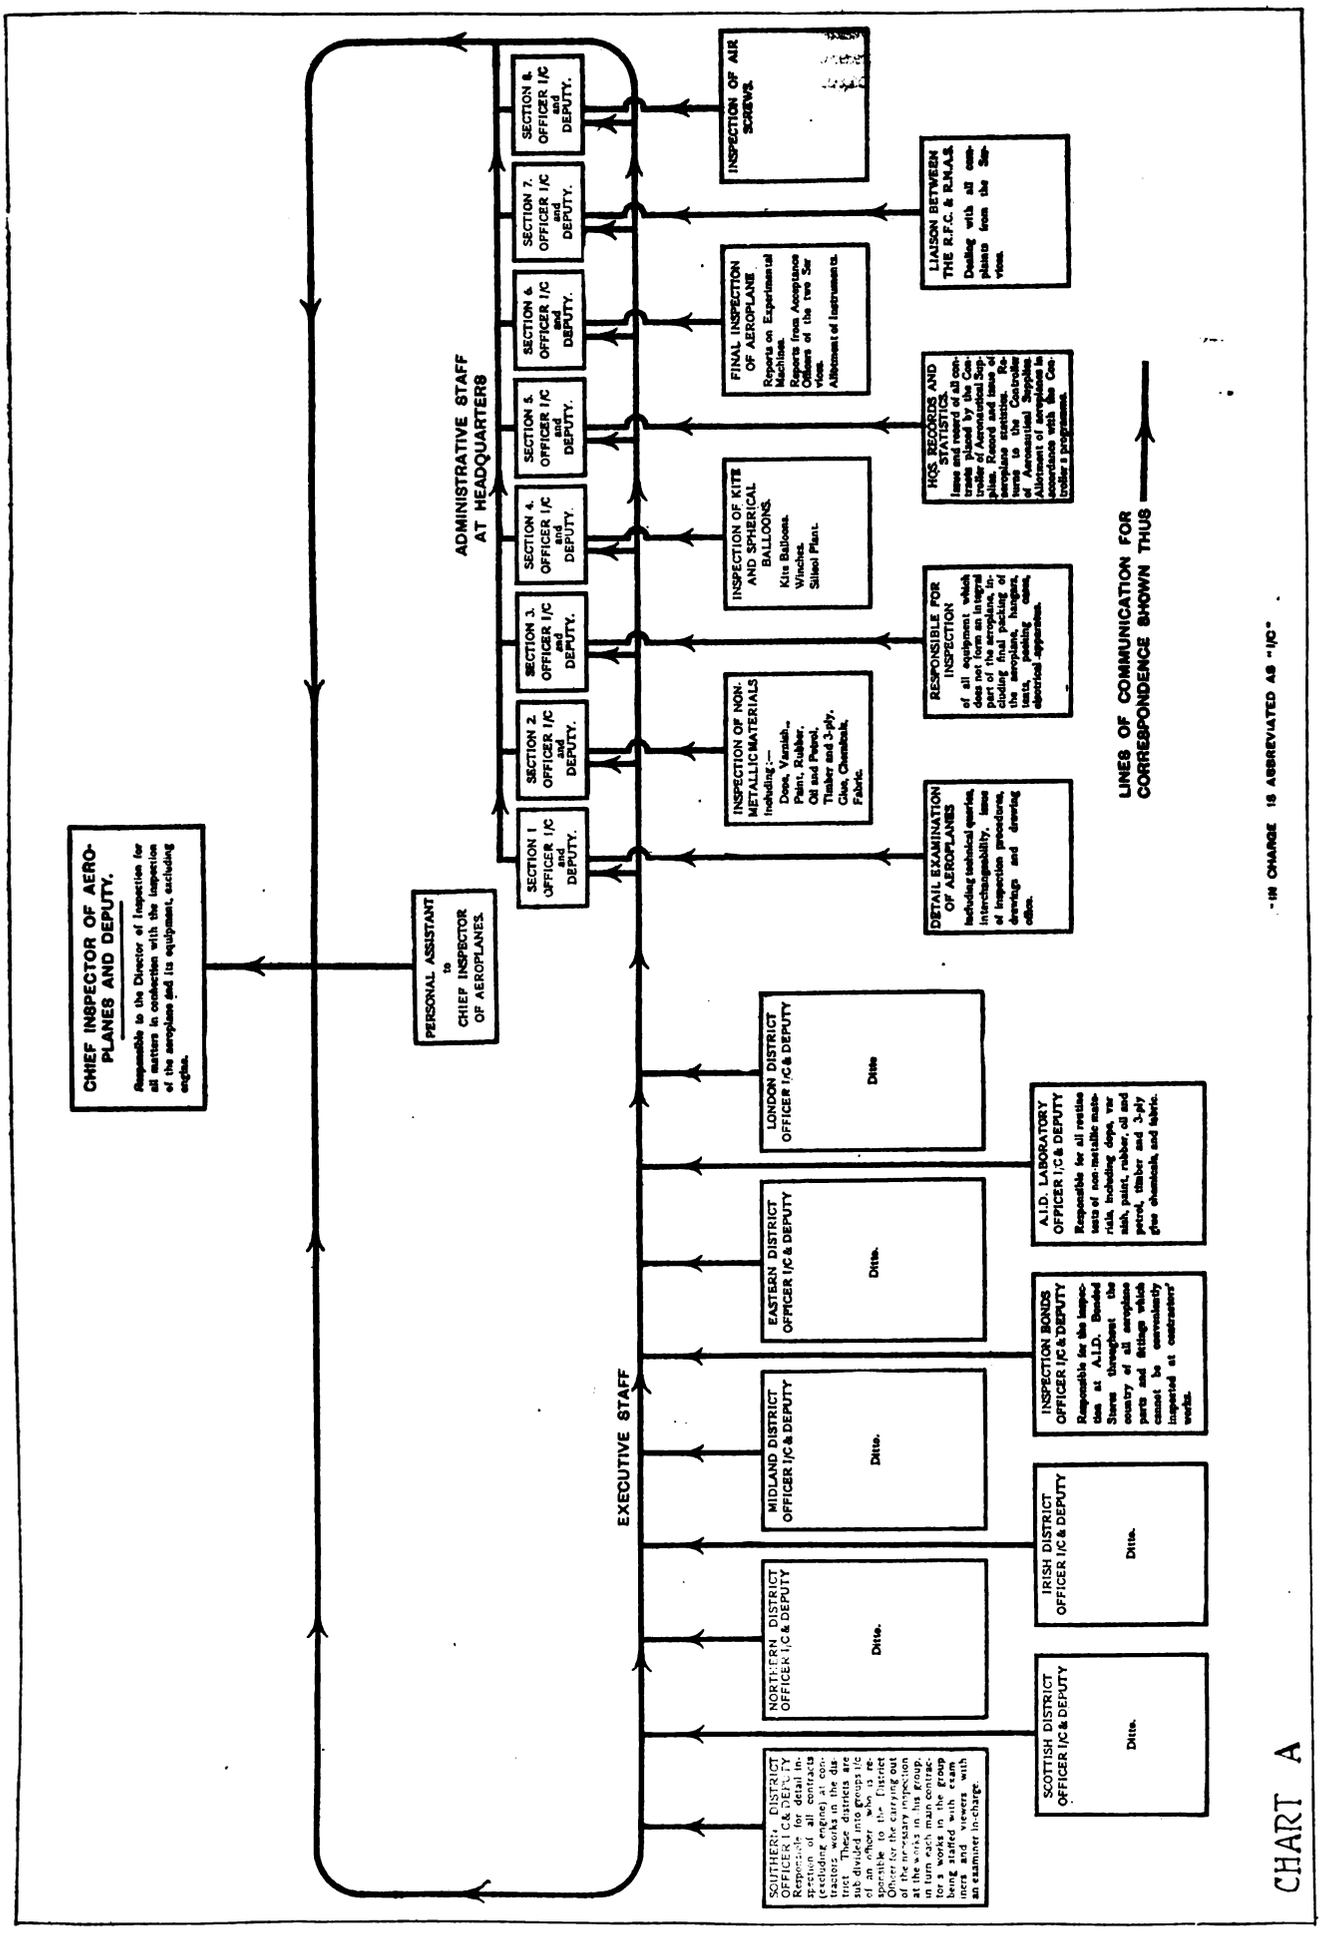


CHART A

Digitized by Google

to an entirely unnecessary degree. Fine limits are required for interchangeability in some cases, but apart from erection considerations are not, as a rule, essential. For example, if two parts are to be bolted together it is, as often as not, quite unnecessary to make the bolts a push fit with something like half a thousandth limit on them. So long as there are two locating points, which may be either locating pins or push fit bolts, the remaining bolt holes may have even a thirty-second clearance on small diameter.

It is extraordinary how long it takes for drawings to reach their final form. The first 50 or 100 are completed, but modifications continue to flow in. It is only by close co-operation from the start that production can reach a proper basis at the earliest date.

Well-Organized Inspection Service Necessary

A great deal has been said about the discretionary powers of the inspector. Government inspectors, formerly, were well known as rigid adherents to drawings. They extracted the last pound without any reference to the effect on production and without using any common sense. This is true in some cases, where the inspector has the necessary knowledge, but not the initiative, to take the responsibility, probably from lack of encouragement. The most dangerous man, on the other hand, is the man who thinks he knows everything and takes too great a burden on his own shoulders. There must, necessarily, in a well organized inspection department, be a head with subordinates under him to control the action of inspectors, and it is but logical that first of all the men who actually visit the works should be given a certain amount of power, those controlling them should be given more and, finally, the head of the department should have full powers.

Fig. 2 and its accompanying charts A, B and C illustrate the organization of a well-known inspection department. It is divided into three main headings, and each of these is again sub-divided into sections, each section being given a different class of work. It is impossible to expect one man to know every branch of engineering; by sub-dividing in this manner it is possible to employ specialists in each particular branch.

I should like to touch on the possibility of employing women on inspection. I have had some very considerable experience of their work and I find they are quick to learn elementary details, *i.e.*, they can be taught to use micrometers intelligently, and naturally easily manage the "go" and "no go" gage. The woman with such a training cannot, however, be given discretionary powers to any extent.

The most economical way to employ women is to place an inspector with discretionary powers over a gang; all cases of doubt are put to him and the rejections carefully scrutinized by him, in order to ascertain why they are necessary. Where the amount of work is large and numbers of girls are employed the rejections should be gone over by a specially appointed inspector, as many of the parts rejected by the women viewers can be made use of for production purposes, either by alteration or by selective assembly.

With reference to women employed on, what may be called, routine work inspection, it is found that some show greater aptitude and greater intelligence than others, and these certainly make excellent inspectors. I can say, however, that with one or two exceptions, I have not yet found them to approach a man who has done his 5 years in the shops and been through a technical college training. It can hardly be expected that this should be otherwise, but it would not be surprising if at no very distant date we shall find women competing in engineering.

Handling Rejections

It is very necessary to arrange a proper system for dealing with rejections. When government inspection is in force I consider that the following procedure should be adopted:

The junior government inspector rejects. This is confirmed by a senior member of the staff, who then labels the part to show the cause of rejection, and he should also express an opinion as to whether the part could be returned to the shops for rectification. The part should then be passed back to maker's viewers, who, if they are in agreement with the government inspector, will take action accordingly; if they are not in agreement the part should then be put on what I term a "pending table" and a higher authority called in for consultation. In a large inspection organization this is arranged for by the appointment of district and traveling officers.

The main object in instituting such procedure is that the reason for rejections may be known at the earliest possible moment to the producer, so that the cause may be removed.

Occasional rejects are not, of course, nearly of such importance as, what I would like to term, bulk rejections. Tools or jigs may become worn and parts may start coming through outside the possible limits. In these cases the earliest possible action is obviously required, to avoid a hold-up.

I recently had an opportunity of studying the French government system of inspection, and it is interesting to note that it is almost exactly on similar lines to that adopted by me. It is not astonishing to note that the number of the inspection staff is in some cases rather less than that found necessary by me in England, as this is readily accounted for by the fact that labor is not diluted to anything like the extent it is in England.

The following brief résumé of the inspection system in this particular industry in France is, therefore, of interest:

The fundamental principles of inspection adopted by the French are almost identical with our own, but their method of applying these principles differs in many details.

The labor is almost entirely undiluted and of a very high average skill. At the works visited very few jigs and labor-saving devices were employed, the individual skill of the workmen being trusted to, with apparent success, as they do excellent work without nearly so much assistance as we give our labor in England.

Ease of production seems to have been most carefully considered by the designers. Details would appear to be designed, primarily, from a manufacturing point of view. It was particularly noticeable that the woodwork was often more elaborate than in English designs, while the metal work was cut down to the minimum.

The number of employees relative to the size of the works appeared to be much higher than in England.

Officer in Each Plant

An officer, with a certain number of subordinates, is stationed at the plant of each main contractor. It is his duty to see that only approved material is used and that each detail part, when finished, is viewed and stamped if approved. Components are again viewed, in many cases several times at various stages, to see that the workmanship is satisfactory and that approved details only have been used. Finally, the assembly of components into a complete machine is inspected at several stages, before the machine is passed, as we do in England.

Material is supplied by approved firms only, at most of whose plants there are resident inspectors, more particularly where high tensile steel or tubing is produced. The majority of the mild steel and practically all timber are inspected on arrival at the main contractors' plants. Finished details and accessories, where sub-contracted for, are supplied only by approved firms and inspected by either resident or visiting examiners.

The practice of returning to a sub-contractor any material which had not been approved before despatch to the main contractor is always strictly adhered to, except in cases of extreme urgency. Timber is usually inspected at the main contractor's plant, but frequently test pieces are taken and sent to headquarters for physical tests. These are, however, considered more in the light of educative information for the timber examiner than as a part of the acceptance procedure.

The process inspection of the various components and the final inspection of the machine appear to be excellent.

With regard to design it would appear that far less sub-contracting is done in France and, therefore, the question of parts made by a sub-contractor fitting a part made by a main contractor hardly arises, and a big saving in jigs and gages results.

The practice of employing only "approved" firms, each of whom has been proved to be capable of making certain parts

AERONAUTICAL INSPECTION DIREOTORATE.

ORGANIZATION OF ENGINE BRANCH.

CHIEF INSPECTOR OF ENGINES AND TWO INSPECTORS.

Responsible to Director of Inspection for the supervision and control of Inspection on Aeroplane Engines.

TECHNICAL AND ADMINISTRATIVE STAFF HEADQUARTERS.

ENGINE SECTION 1. O.I/C & DEPUTY.
TECHNICAL QUERIES ON ENGINES.

- Inspection.
- Defects, Improvements.
- Ease of production.
- Manufacture, viz., drawings.
- Limits, gauges, Interchangeability
- Material specifications.
- Methods of inspection, bench testing
- Maintenance and correction of drawings throughout Inspection Staff

ENGINE SECTION 2. O.I/C & DEPUTY.
MATERIALS (METALS).

- Technical queries on material inspection.
- Defects, Improvements, ease of production
- Manufacture from raw materials, viz.:— Forging, stamping, casting, swaging, &c.
- Methods of inspection, physical tests, analyses, micro-photography, and investigation of failures.
- Inspection of machine tools and electrical plant.
- Control of two inspection groups as a District Officer

ENGINE SECTION 3. O.I/C & DEPUTY.
RECORDS, ALLOTMENT & CERTIFICATION

- Allotment of Engines, Engine output returns, and progress reports.
- Certification of issue vouchers and % payments for Engines on Test.
- Maintenance of Log-books and Engine Records.

ENGINE SECTION 4. O.I/C & DEPUTY.
LIAISON (MILITARY).

- Functioning of Engines in Aeroplanes.
- Liaison with R.F.C. Acceptance Branch and A.I.D. Districts to maintain efficiency.
- Technical queries on Engine Installations in Aeroplanes.
- Liaison with R.F.C. Testing Squadron and all R.F.C. units as required

ENGINE SECTION 5. O.I/C & DEPUTY.
LIAISON (NAVAL).

- Liaison duties similar to those of Engines Section 4 with R.N.A.S.
- Adviser to Chief Inspector on previous procedure.
- Administrative questions concerning attached Naval Staff.
- Responsible executive officer for an inspection group and a main contractor on similar lines to a district officer

ENGINE SECTION 6. O.I/C & DEPUTY.
PERSONNEL.

- All questions relating to appointments, rates of pay, increases, promotion, transfer, and release of Engine Branch Personnel.
- Administrative questions of a general nature affecting the Branch.

EXECUTIVE STAFF — DISTRICTS.

DISTRICT 1	DISTRICT 2	DISTRICT 3	DISTRICT 4	DISTRICT 5	DISTRICT 6

OFFICER-IN-CHARGE AND DEPUTY FOR EACH DISTRICT.

Responsible for inspection of all Aeronautical Supplies Contracts for Engines and Materials (Metals) at contractors and sub-contractors in the District.
Inspection is divided into two heads, Resident and Visiting.
A resident staff is maintained at the large main contractors; visiting staff or "floaters" being responsible for the inspection at smaller contractors and sub-contractors.

CHART B

correctly before being placed on the "approved" list, and can therefore be trusted to repeat correctly such parts, would seem to have had most excellent results and to be worthy of early adoption to a much greater degree in this country. I cannot emphasize that too strongly.

It is obvious that to obtain increased output we must develop and expand the works of existing contractors. The conditions in this country will, therefore, approximate more and more closely to the conditions in France, in that we shall have to rely upon the contractor for detail examination and concentrate our examiners on process inspection of components and on assembly. It is, therefore, urged that this expansion of the main contractors be very closely coupled with a strict control of the sub-contractor. The sub-contractors who have successfully turned out certain details with a low percentage of rejections should concentrate on these details and be expanded as necessary, new firms only being approved when all other sources of supply fail, and firms with large percentage of rejections removed altogether from the list. It is thought that much more might be done in this country to educate firms who waste material by their high percentage of scrap, for instance, 60 to 70 per cent of rejects on such things as nuts, or failing that to shut them down and make greater use elsewhere of the labor thus released.

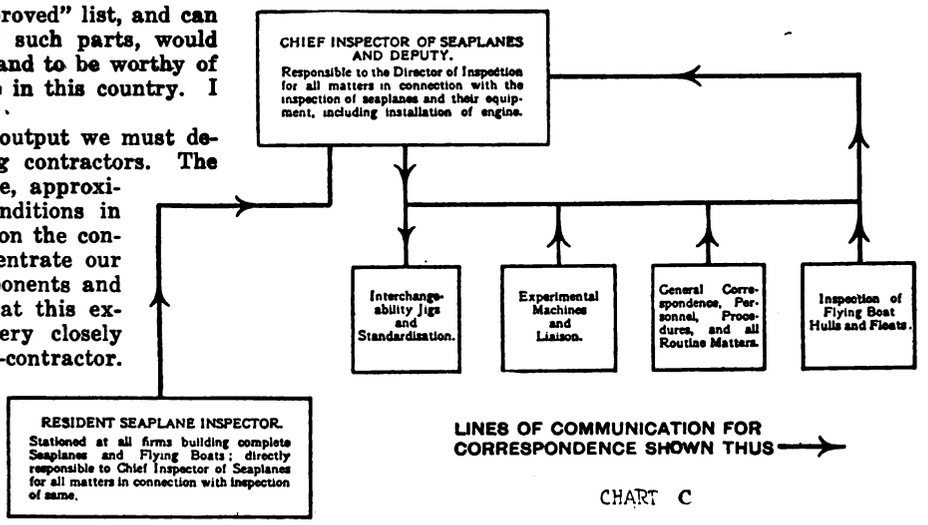

CHART C

Inspection is essential to obtain efficient output. It is the only method whereby the directors of a company can ascertain the quality of the firm's output; it is their only safeguard that money, time and material are not being wasted in the production of scrap; it is a check on their purchasing department; it is a check on their design and drawing office, and it is even a check on their chief engineer, to whom the inspection branch is responsible. Facts will always speak, and the inspection department can at any moment produce figures showing rejections at any stage from the purchased raw material to the completed and finished article.

I do not consider that nearly enough attention has been given by managing directors and managers to the valuable data available in the inspection department.

It has been suggested to me that a full government system of inspection is but a duplication of work. For a long time I have had available a record showing rejections by the firms and rejections by me. These figures, of course, also give the percentage rejections on the total output, and they must, surely, be of vital importance, not only from the output point of view, but financially. A little more money spent on inspection, not only increases dividends, but brings in more orders. The better the article, having due regard to cost, the greater its popularity with the purchaser.

In talking of selective inspection it must be remembered that if we assume 10 per cent as a fair figure for rejections on a certain class of article, if the firm's view-room is adequate, some 9 per cent of that total of 10 per cent should be rejected by the firm, and something like 1 per cent—less preferably—should be rejected by the government inspector. In that case selective inspection may be safe. But many firms have asked to apply selective inspection where they are getting some 20 per cent scrap and where nearly 19 per cent of that is rejected by me and not by the firm. The whole object I have before me is to encourage the firm's view-room, but very often because they know a government inspector is going through everything, they do not care. They think they have no interest in the job at all, and therefore it is up to us to encourage the firm's view-room to have an interest in the work. I think the best way is to adopt selective inspection purely on facts, *i.e.*, according to the percentage rejected by the firm compared with that rejected by the government inspector, and in that way a good view-room will result.

The inspector, as a rule, is nobody's friend. This is not always his fault, it is a fault of the whole system, he should be encouraged to be human. He must not be on unduly intimate social terms with the production staff, but he must be capable of dealing with them with tact and cordiality.

I am certain that if more attention were paid and more encouragement given to the class of man employed by firms for this purpose, much better results would be obtained.

So far as I, personally, am concerned, I invite criticism and co-operation and am at all times willing to listen to suggestions which will further output.

[*Part II to be published next week*]

Ideal Road Illumination

DISCUSSING the automobile headlighting problem in *Electrical Review*, Evan J. Edwards, manager of the engineering department of the National Lamp Works, has the following to say regarding an ideal system: "The machine must be equipped so that in passing other machines it is capable of giving good road illumination up to 75 ft. ahead of the car and of a width sufficient to cover the roadway, say 15 or 20 ft. The light from the upward angles should be reduced to the absolute practicable limit. The upper limit of the high-intensity beam should be depressed about two degrees below the horizontal as a factor of safety to insure no-glare under practically all conditions of road curvature and loading of the machine. It would give good road illumination nearby which is essential to safety in passing. It would eliminate glare by the elimination of the light in the angles where might be found the eyes of the approaching driver. There can hardly be a question that such a system would be satisfactory insofar as the passing of other vehicles is concerned.

"Such a system, however, if fixed in position and the only one to be provided, would be very unsatisfactory from certain other standpoints. It would not have sufficient throw to permit of speeds that are often desirable. It would not give warning at a distance to the approaching driver on a cross-road. It would not give pedestrians warning of the approach of the vehicle. It would not give the sense of security and pleasure in night driving that is obtained by the illumination of distant objects in the upward angles. It would not allow a satisfactory range of vision when approaching the foot of a hill. All of these disadvantages are important and some of them are materially concerned in the question of safety. All of them are disadvantages common to all systems where the upward light is reduced or eliminated, and are serious to a degree inversely in proportion to their effectiveness from the standpoint of elimination of glare. None of these disadvantages appear in the standard paraboloid headlights; therefore, it would seem that the ideal system would be one capable of more than one kind of distribution. The points involved are of sufficient importance to bring the conclusion that a satisfactory automobile headlighting system for both country and city driving can never be obtained with one fixed distribution of the light."

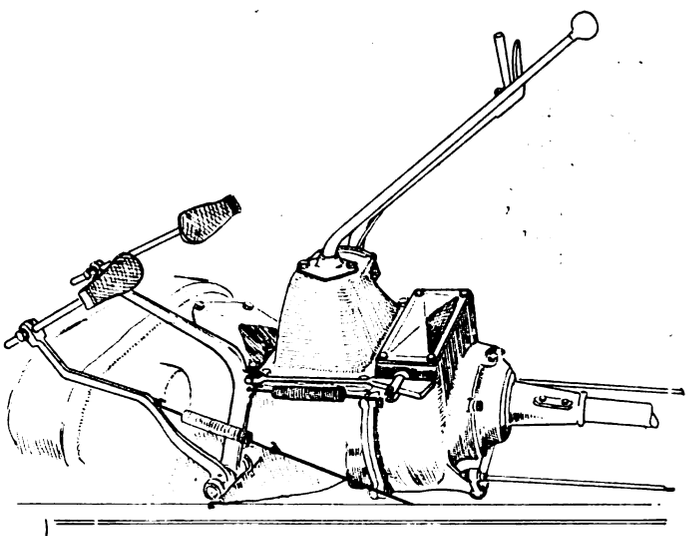
Mechanical Features Revealed by the Show

(*Continued from page* 109)

a lower cost than other cars giving similar service. The Overland company has been producing small, low-priced cars for years, but the present model is avowedly an attempt to beat its best previous achievements and to create a machine for which there will be an enormous market.

The feature which strikes one most upon an inspection of the chassis is the running gear construction.



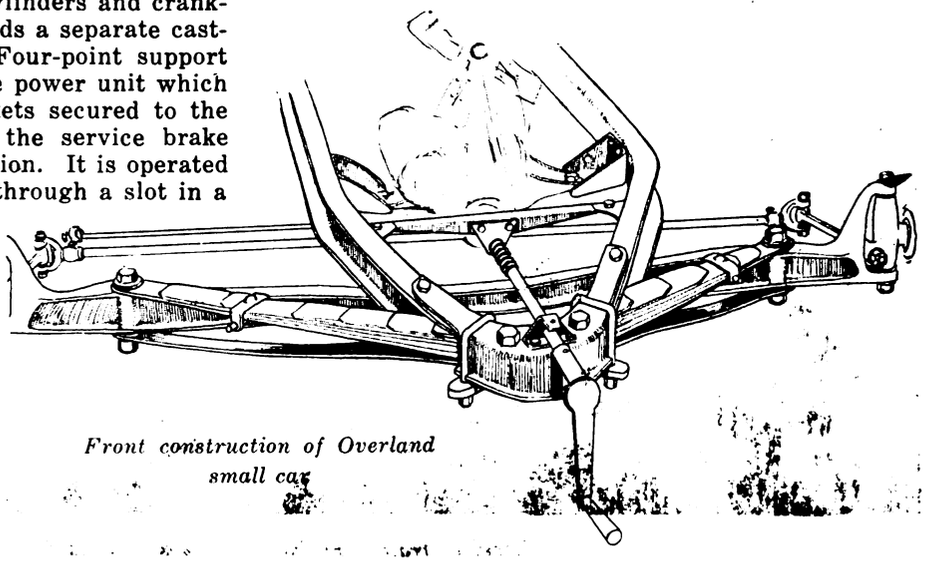
Rear construction of Overland small car

The frame is made of channel steel, with the open side of the channel turned to the outside. The frame members are joined at the ends in such a way as to give a tapering front and rear. This frame is supported on the axles by four quarter-elliptic springs extending underneath the tapering portions. By thus inclining the springs it is possible to have them act as thrust members or radius rods and at the same time bring the load close to the wheels so that the load on the axles is greatly reduced. The front springs are entirely in front of the axle and the latter is pulled by them.

Has Standard Type Engine

It has already been stated in these columns that the four-cylinder engine has 3 x 4-in. cylinders. It is of what has come to be regarded the standard type of engine for low-priced cars, with the cylinders and crankcase in one casting, the cylinder heads a separate casting and the oil base a pressing. Four-point support is used, there being four feet on the power unit which rest upon comparatively long brackets secured to the frame. An interesting feature is the service brake which is inclosed with the transmission. It is operated by means of a wedge which passes through a slot in a bar, operating against a roller in same. This wedge and its pull rod are in a single piece of the outline of a rifle, which connects directly to the brake pedal. Such simplification of the control linkage is especially valuable in a low-priced car where not much work can be spent on the joints and where a large number of joints is sure to result in noisy operation at an early stage in the car's life.

In the higher-priced class engineering considerations must sometimes give way to whims of the buying public or to their idea of the fitness of things. Thus we understand that the Packard control box on the steering post had to be discarded because the buying public did not fancy its appearance. From an operating standpoint it seemed to be a thoroughly sound construction in that it brought all of the controls in a very convenient position for the operator. From an artistic



Simple inclosed service brake on Overland small car

standpoint it was certainly not a very happy conception and inasmuch as most of this class of cars are driven by chauffeurs, attractive appearance makes more of an impression with the people who control the purchase than does operating convenience with which they have little or no concern.

Thermostatic Temperature Regulation Increases

Temperature regulation, chiefly automatic by means of thermostats, is becoming a more important factor. The most usual arrangement is to have the thermostat control a by-pass on the cooling water circuit, but in some instances it acts on shutters on the radiator. In fact, heat control is one of the livest subjects in automobile engineering at the present time, and the future is sure to bring further developments.

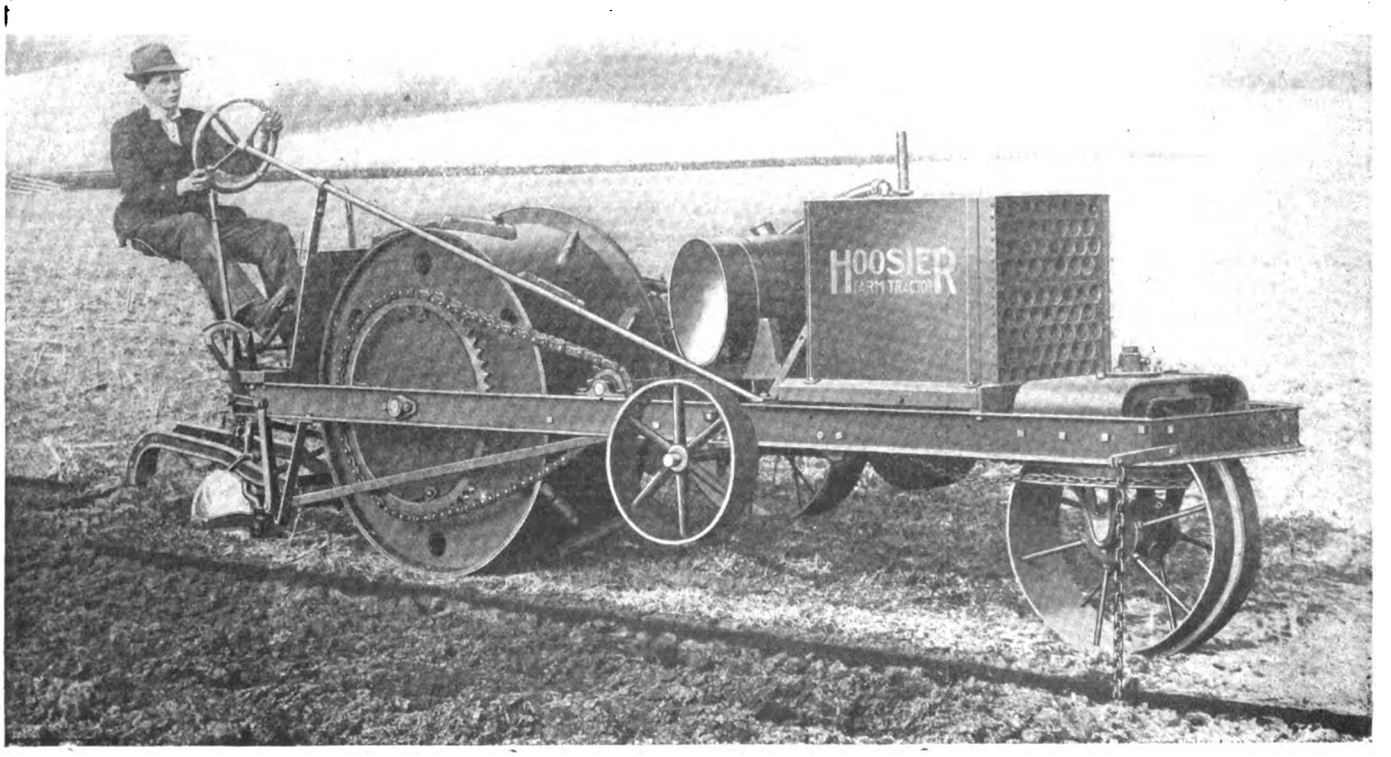
The Hoosier Farm Tractor

A Boiler-Plate Drum With Driving Lugs Serves as Drive Wheel—Also Has Two Non-Driving Wheels

A SMALL tractor suitable for farms of from 100 to 300 acres is manufactured by the Leo Rumely Tractor Co., La Porte, Ind. It is an assembled proposition and at present is built on a small scale only.

The engine is a Waukesha tractor engine and sets on the frame directly over the driving axle, next to the single drum type driving wheel. The tractor is of the three-wheeled type, having a single driving wheel at the rear, a swiveled steering wheel at the front and a guide wheel at the side. The engine is of 3¾ in. bore and 5¼ in. stroke and is rated by the manufacturers at 28 hp., but the Rumely company's rating of the tractor is only 18 hp. at the belt and 8 hp. at the draw bar. The engine is of the regular Waukesha type as built for truck and tractor work, and it is not necessary to go into a detailed description of it here. It is provided with a centrifugal governor which maintains its speed within well defined limits. A Kingston carbureter is fitted and is provided with a Bennett air cleaner so that the engine is protected from dust and grit. Ignition is effected by an Eisemann high-tension magneto of the waterproof type. Batteries are not needed for starting. No attempt is made to use kerosene, as the fuel consumption is comparatively low and it is figured that there will be less trouble with the engine with gasoline. For cooling the engine a large tubular radiator is provided and carried at the front of the tractor frame. This has a capacity of 26 gal. and has an 18 in., high speed, ball bearing fan mounted back of it.



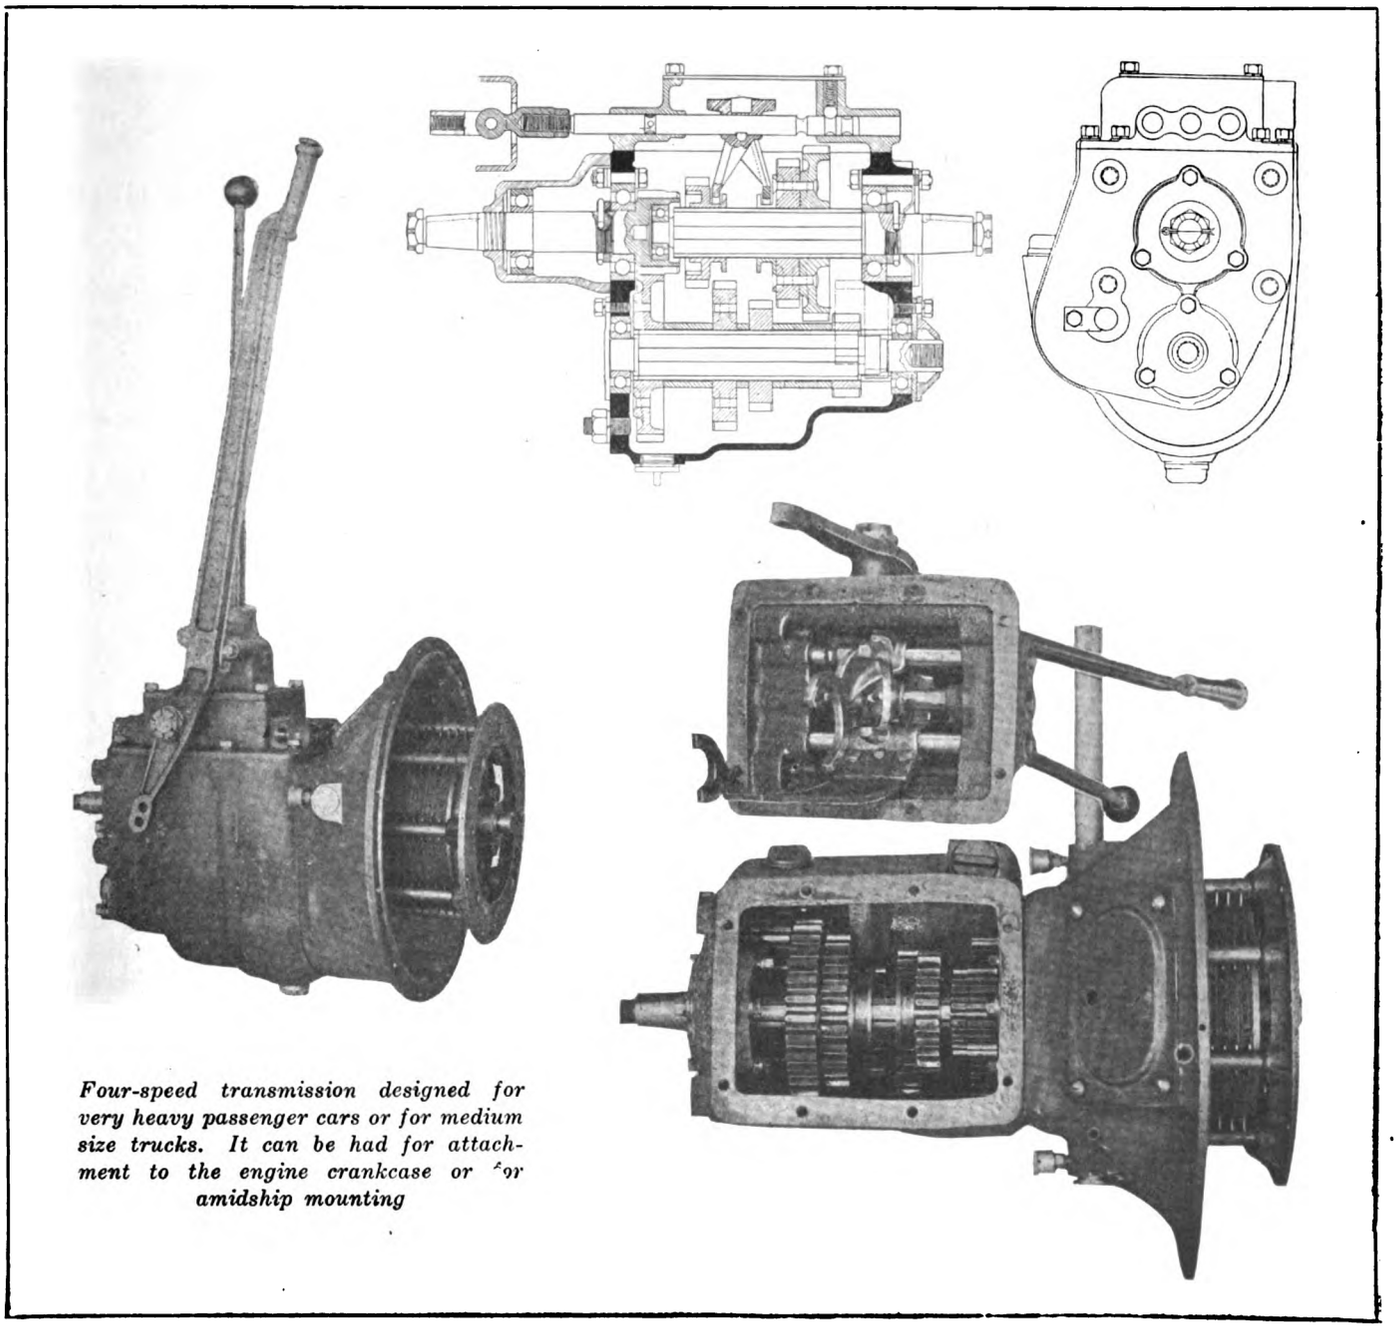
The power is transmitted from the engine through a Borg & Beck dry disk clutch, inclosed in the engine flywheel. The transmission affords only one forward speed and one reverse, the maximum speed being 2½ m.p.h., and this can be cut down by means of a throttle to 1¾ m.p.h. The gears are made of chrome nickel steel, have cut teeth, are hardened and run in a bath of oil. They are inclosed in a cast iron case. The transmission gears are mounted on double row ball bearings and the case is provided with a cover plate which gives ready access to the gears. The final drive from the transmission to the driving wheel is by a 1¾ in. roller chain which runs over hardened, cut steel sprockets. The driving wheel is 54 in. in diameter and has a 24 in. face. It is provided with detachable driving lugs. The axle is mounted in roller bearings 9 in. long. Of the two non-driving wheels the front one has a diameter of 30 in. and a 10 in. face and the one on the side a diameter of 40 in. and an 8 in. face.

Rear view of tractor, showing location of the engine

All of the wheels of the Hoosier tractor run on firm ground when the machine is used for plowing, none of them running in the furrow.

The draft on this tractor is unusual. The draw bars are hinged to the frame quite a distance in front of the rear axle

Hoosier tractor hauling two-bottom Grand Detour plow



Digitized by Google

and are inclined downward. By means of a lever convenient to the driver the height of the rear end of the draw bar can be adjusted within wide limits. In this way it is possible to adjust the depth of plowing from the driver's seat on the tractor. A special Grand Detour plow is used with this tractor, the plow beam being hitched directly to the draw bar. A plow lifting device of new design has recently been worked out, which is not shown in the illustrations. It is a power-operated device, a chain from the driving mechanism running over a chain pulley close to the driver's foot. Adjacent to this pulley there is a pawl and ratchet mechanism, the pawls of which are ordinarily held out of engagement by means of a trip. By operating this trip the driver can engage the pawls and cause the plows to be lifted out of the ground by means of power from the motor. This device makes it possible to make short turns and the plow may be backed into fence corners.

In addition to plowing, the Hoosier tractor is adapted for all sorts of belt work. It is fitted with a 20 in. pulley having an 8 in. face, and the pulley is located conveniently at the side so that the belt can be easily slipped on and off. The frame of the tractor is made of 5 in. channel steel. The weight of the whole tractor is 3900 lb.

New Fuller Gearset

THE great majority of passenger cars and practically all of the smaller trucks are fitted with three-speed gearsets, but there is a certain demand for four-speed transmissions for heavy trucks and passenger vehicles. To meet this demand Fuller & Sons Mfg. Co., Kalamazoo, Mich., have developed the transmission illustrated herewith. It is of the selective type, mounted on ball bearings throughout and has splined primary and secondary shafts. Gear and brake levers may be mounted directly on the cover plate, as shown in some of the illustrations, though if the chassis layout requires this, the gears may be shifted through pullrods, as also illustrated.

Four-speed transmission designed for very heavy passenger cars or for medium size trucks. It can be had for attachment to the engine crankcase or for amidship mounting

Engineering Progress in War Time

IF the history of automobile development since the beginning of regular manufacture were divided into a considerable number of equal periods and the advance in design made in each determined as nearly as possible, it would be found that the periods of greatest progress corresponded to those of low commercial activity. When market conditions are good; when the production of cars runs behind the demand, there is little incentive to make extensive changes in design, as these always occasion heavy outlay for new tool equipment and interfere with production. Besides, what is the use of making improvements when the cars already are so good that the buying public cannot get enough of them? But when trade slackens off and when purchasers no longer are glad to get any car in reasonable time but are most exacting in their demands the manufacturer feels the need of having his product up to date in every respect. There is the further consideration that improvements or new models can be introduced with much less trouble at a period of slackness than when a factory is working to its limit.

While the war lasts the demand for passenger cars will undoubtedly remain below normal and competition will be quite keen. It will be difficult to sell cars which do not conform to the requirements of the times. During the early stages of the war there has been a tendency to drift along, largely due to the unsettled conditions that obtained, but now that it is fairly plain what we are in for we may expect renewed activity in development work, as it will be every manufacturer's aim not only to fortify himself for the somewhat trying times immediately ahead but also to place himself in position to take full advantage of the boom that is sure to set in with the return of peace. New models and changes of a radical character should be given a long try-out before being put in regular production; therefore, makers should not delay shaping their plans. Although nobody can tell what the future holds and how far the end of hostilities is still off, in view of the fact that most British manufacturers already have their post-war models ready it is not too early for our own manufacturers to begin preparing for business under the somewhat changed conditions upon the return of peace.

Motor Plows vs. All-Purpose Tractors

HORSES on the farm are what might be called multiple purpose machines. They draw all of the different implements used for preparing the soil, seeding, cultivating and harvesting; they draw the wagons in which produce is carried to market and farm requisites home, and they operate various types of stationary machines through so-called horse powers. One of the fundamental problems of power farming is whether it is the best policy to design a machine that is capable of doing every kind of work that the horse usually does on the farm, or whether special machines should be developed, at least for the more important classes of work, such as plowing, road hauling, etc.

An all-purpose machine must naturally be a compromise and cannot be as efficient in any particular service as a machine specially designed for that service. In the manufacturing industries this is the age of the special machine. Large boring mills and drill presses, for instance, are designed to work on only one particular machine part, and the advantages of this method are so overwhelming that no one would think of using stock lathes and drill presses—the all-purpose machine tools—where many thousands of parts of the same kind are wanted.

However, in farming the conditions are entirely different from those in manufacturing. If plowing could be done from the beginning of the year to the end it would certainly be best to design machines to do nothing else. As a matter of fact the time occupied in plowing on the average farm is only 20 to 30 days per year. Therefore, a motor plow would be idle more than 90 per cent of the time. It is true enough that a piece of machinery when not in use does not require to be fed, as does a horse, yet it

Digitized by Google

occasions expense, because there is money invested in it and this money has interest-bearing power.

It is certainly a highly desirable thing to have machinery operate as efficiently as possible, but where expensive machinery is involved it is equally, and perhaps even more important, that it be kept at work as nearly continuously as possible. This phase of the subject may not have received much attention in farming because there seems to be little possibility of changing the rather rigid routine of the farm year. On the other hand, managers of electric central stations make every effort to "flatten out" their load curve, which means doing the greatest amount of business with the least equipment. The advantage is that the interest charge per unit of electric energy sold is reduced.

This same principle holds equally well with respect to farm machinery. It does not matter whether the farmer uses his own capital or borrows money for purchasing the implements, the capital tied up might bear interest, and if the equipment is not used the interest charge is a loss. The fact must also not be lost sight of that farm machinery during periods of nonuse frequently does not receive proper treatment and in consequence depreciates rapidly.

In view of the above facts there is every likelihood that the development of agricultural power machinery will be along the line of the all-purpose tractor, because a fair degree of efficiency can be obtained with such a machine in the different lines of work for which it is adapted and the farmer does not need to make heavy investments in a variety of machines for which he has no work the greater part of the year.

War Time and Shows

THE show is a success. True, there are not the choked aisles and the surging crowds of past years. There are not the groups of youthful catalog collectors nor the fancy dress parades. On the other hand, there is an intelligent attendance of potential buyers and business people. As a show of the products of a great industry the Palace is a veritable mart of trade for those within the industry itself. The manufacturer, the jobber and the dealer are naturally all there in large numbers and this year has witnessed no great cessation in their activity.

The public itself is amazed at the show. It has been fed on stories of what the war has done to the automobile industry and expected to see this year marked effects of the war upon the exhibition. Instead visitors see a show that is just as great as, if not greater than, any of its predecessors. Here are better products, more efficient vehicles to help in transporting busy Americans from place to place. The great essential of individual transportation, the automobile, is here more highly developed, more artistically dressed than ever before.

A noticeable fact is that the opening day had the least attendance. The throngs were conspicuous by their absence. Since that opening day the attendance is gradually building up and becoming larger. More business is being done and the prediction that the opening of the show season would witness a restoration of confidence is being borne out.

War time, instead of being a bad time to hold the show, is the real time in which its merit becomes evident. "Speed up the industries!" is the battle cry that will lead the nation to victory, and anything which has a stimulating influence will tend to speed them up.

Strong-hearted industries, capable of working at more than normal pace, capable of supplying first government needs and then their own without a let-up in efficiency and capable of not only handling all the work of the war, but the work of peace besides, are the ones that are going to help most. The show is a stimulant and its success has proved its strength.

Demountable Wheels for Motorcycles

NOW that motorcycle wheels have been completely standardized, with the exception of the hubs, there is some chance of demountable wheels coming into use the same as on automobiles. It is hardly to be expected that a spare wheel will ever be carried on a motorcycle, as it could not be stored conveniently, but wherever motorcycles are used in considerable numbers and subjected to severe service, demountable wheels would simplify the repair problem. The advantages of demountable wheels would no doubt stand out most strongly in military service in which wheels fail frequently. Following automobile precedent, there would probably be two hubs, an outer hub forming a permanent part of the wire wheel and an inner hub containing the bearings and carrying the driving means. To this inner hub the outer hub would be secured. Only one type of outer hub would be used. The inner hubs would be different for front, rear and side car wheels, but each type of inner hub would have its outer contour designed to accommodate the standard design of outer hub. One of the most important problems in connection with such demountable wheels is that of the driving connection between the two hubs or between the chain wheel and the outer hub of the rear wheel. The parts must go readily together, yet there must be no slack in the connection.

The chief advantage in a demountable wheel for motorcycles in large services is that it obviates extensive loss of use of the machine due to failure of wheels. If a wheel breaks it is simply removed from the inner hub and another one is substituted, which is the work of a few minutes, whereupon the machine can be replaced in service. The old wheel can then be repaired if this is thought worth while, or else junked. Where ordinary wheels are used not only must three different sets of repair wheels be kept, but each wheel, since it contains the rather expensive bearing hub, ball bearings, etc., represents a greater investment than a demountable wheel. Nowhere is there such a need for demountable wheels as in war operations and the subject will undoubtedly receive full consideration in the design of the army motorcycle.

Standards Committee in Busy Session

Action Taken on an Unprecedented Number of Subjects — Aeronautic, Motorcycle, Roller Chain, Data Sheet, Miscellaneous and Tractor Divisions Get Reports Adopted — Lack of Quorum at a Late Hour Prevents Adoption of Marine and Tire and Rim Division Reports

ONE of the busiest sessions ever held by the S. A. E. Standards Committee was that at the New York headquarters on Wednesday. More than one half of the session was occupied by reading, discussing and voting on the voluminous report of the Aeronautical Division which contained no less than twenty-three proposed standards. The word standards, however, is not quite to the point in this connection.

It is realized that aircraft engineering is as yet in a state of rapid development and what may seem best to-day may be greatly improved upon within a year. Therefore it has been decided to refer to all of the completed work of the Aeronautic Division as "Recommended Practice" and not standards.

Upon the opening of the meeting by Standards Committee Chairman Utz, Standards Manager Hanks read his report. It reviewed the work done by the Standards Committee in co-operation with the Government, toward the development of the Liberty truck and in the standardization of certain features of motorcycles.

After a certain amount of work had been done along each of these lines the Government took complete charge and selected committees of designing engineers who continued the work of design at Washington.

Need for Speed Was Urgent

Taking up the subject of aeronautic standards Mr. Hanks said:

The aeronautic war standards were required to be turned over to the Government in the shortest possible time. It was not practical to ask the Government to wait 6 months for the S. A. E. to pass the standards through the usual routine. A short cut was authorized by the council, permitting results arrived at at any division meeting to be released immediately to the Government Bureaus needing the standard.

The Government representatives were always present at these meetings, so they were in the closest touch with all conditions from both engineering and manufacturing standpoints. On all these recommendations which went to the Government by short route, a notation was entered at the bottom of each, reading:

> This practice has been recommended by the Aeronautic Division of the S. A. E. in co-operation with representatives of the U. S. War Dept. (or other departments co-operating.)
>
> If, for any reason, your requirements cannot be brought into harmony with this practice, please notify promptly the Society of Automotive Engineers, 29 West Thirty-ninth Street, New York City, returning this sheet with comments thereon.
>
> This practice recommended represents the consensus of opinion of the advising engineers as of (date on which the recommendation was made).

In order that these recommendations might be of the greatest value and be available when wanted, they were printed or mimeographed on standard letter-size paper and placed in loose leaf binders with the S. A. E. emblem on the cover, and sent to those in charge of the various Government bureaus.

In much of the standardization work heretofore attempted, a careful review of American practice with American engineers was all that was necessary. This procedure did not fully meet the requirements in the aeronautic field, as our airplanes are going abroad and the experience of both the foreign builders and ourselves must be co-ordinated. The I. A. S. B., composed of engineering representatives from the United States, Canada, England, France and Italy has been the medium for this co-ordination, and many S. A. E. members are on this board.

The Aeronautic Division has held a total of 24 meetings during the year 1917, including sub-committee meetings. The largest number of meetings held by any Division in previous years was by the Engine and Transmission Division, who had 7 in 1916.

The amount of business transacted by the Standards Division is illustrated by their offering for your consideration to-day a list of some 65 recommendations. In 1916 a total of 38 standards were passed and 45 meetings held. In 1917 there were 109 meetings, and the total number of standards passed for final action was 122.

Aeronautic Division Report

First the report of the Aeronautic Division was taken up, C. M. Manly, chairman of this division, presenting it. In several sections of this report, references were made to government departments in the capacity of purchasers, and it was decided that it would be better to make the recommended practice of general application and to this end substitute the word "customer" for the Signal Corps or other department of the Government.

In the cellulose nitrate report the wording "according to the standard method of the Bureau of Ordnance" is to be replaced by "the Standard Government Method of the Abel Stability Test." The Signal Corps absolutely objects to the use of tetrachlorethane and an item was therefore inserted to the effect that dopes containing tetrachlorethane will not be acceptable. With these amendments the report was adopted.

Specifications Not Ideal But Practical

Dr. Smith of the Bureau of Standards said that the specifications were not ideal but they were practical. The Signal Corps was drawing up specifications for its own use which were being based on the report of the Division. It was hoped to incorporate in these specifications a test for durability, but the work in connection with this test had not yet been completed. Later on, it was the intention to also draw up specifications for a non-inflammable nitrate dope on which tests are now being made.

Dr. Percy Walker of the Bureau of Standards presented the report on spar varnish specifications. One objection was the great latitude allowed in the temperature range in drying the varnish for the bending test. It was decided by the subcommittee to limit the range to 21-24 deg. C. instead of from 21-32 deg. C. as originally proposed. It was stated that Mr. Hanks had sent out a circular to different varnish makers asking for criticism of the proposed change and that the comment made had on the whole been favorable. Mr. Walker, however, pointed out that there was no lack of criticism of the work of the sub-committee and that the hot water test proposed had met with particularly strong objections. Mr.

Digitized by Google

Costello, representing the Signal Corps, said that there was quite a possibility that they would omit the hot water test from their specifications. Grover Farnsworth, an aircraft engineer, on the other hand, agreed with Dr. Walker regarding the utility of this test. The report was adopted without further amendments.

Requirements of Good Glue

Presenting the report of the sub-committee on glue specifications, Mr. Manly said that he expected more opposition to this report than to any other. One change that was suggested and accepted without opposition was that wherever the term "the government" or the name of any department of the government appeared, it should be replaced by "the customer."

The report as presented specified that "the glue must be a high grade hide glue," but it was brought out that hide glue is at present practically unobtainable in this country. Glue is manufactured from hoofs, bones and other parts of the animal and it seemed to be the opinion among glue manufacturers that the part from which the glue is made is not such an important factor as the process of manufacture. To get around this it was suggested that the word "hide" be replaced by the word "animal".

Another point to which objection was raised, was the requirement that the strength test of the glue be made by means of two pieces of maple or birch having a shearing strength of at least 2400 lb. per square inch. It was pointed out that if the longitudinal shearing strength was meant, this seldom exceeds 1500 to 1600 lb. per square inch and that woods of this kind showing 2400 lb. shearing strength were absolutely unobtainable.

Mr. Manly said that there had been some discussion regarding this figure, which had been based on information furnished by the National Forest Products Laboratory. Another suggestion made was that the second illustration in the report, showing a double shear test block, be omitted. This suggestion came from Mr. Manly who said that he had had very poor results from test blocks of this kind, as the blocks would invariably spread and the glue not fail under shear but rather under tensile stress. It was finally decided to refer this report back to the committee with instructions to gather information as to what shearing strength could reasonably be specified for the test pieces of maple or birch.

Specifications for Steel Wire

In connection with the specifications of round high-strength steel wire, objection was raised to the torsion test. According to the specifications, a sample of the wire not less than 10 in. long and gripped by two vises 8 in. apart, must be capable of being twisted a number of times equal to the constant 2.7 divided by the wire diameter in inches. It was asserted that it was absolutely impossible to get large diameter wire which would meet with this requirement.

It was therefore agreed that the number of turns which the sample must be able to stand should be equal to a constant factor to be agreed upon between the customer and the manufacturer, to be divided by the wire diameter in inches. The adoption of this amendment also made it necessary to eliminate the third column in a table accompanying the report. With these changes the report was adopted.

Next the subject of non-flexible steel wire cable was taken up and quite a spirited discussion ensued regarding the best method of rust-proofing the wire. The report as presented required that the cable be uniformly coated with pure tin. Mr. Manly stated that the U. S. Government preferred galvanized cable and that his firm used such cable at the present time. The International Aircraft Standardization Board, on the other hand, favors tin covered cable. Mr. Erickson of the Canadian Aircraft Board, who represented the I. A. S. B. at the meeting, said that tinning the cable not only insures greater strength as compared with galvanizing, but also facilitates soldering. He stated that differences in strength of as great as 8 per cent in favor of the tin cable had been shown.

Mr. Manly said that he had been discussing the matter with Mr. Horn of the Roebling Steel & Wire Co. who favored the galvanized cable, while other makers seemed to favor the tin cable. The Roeblings were willing to make either kind, but were very anxious that one of the two be decided upon so that it would not be necessary to maintain equipment for both tinning and galvanizing. Mr. Birdsall stated that experience had shown that galvanizing—he referred to hot galvanizing—always weakened a wire cable or a chain cable. Mr. Erickson said that the chief reason why the I. A. S. B. favored tinning was that the tin formed a better base for solder. It was moved that the word galvanized be substituted for the phrase "coated with pure tin" and also that a footnote be inserted to the effect that the method of galvanizing (if used) be specified by the customer. This amendment was adopted.

A further amendment was in regard to the torsion test which was amended to correspond to the torsion test for the round high-strength steel wire, it being left to the customer and manufacturer to agree upon the number of turns which the test specimen must be capable of withstanding. The report with these amendments was adopted.

American Cable Proves Best

Reports on flexible 6 x 7 and 7 x 7 steel wire cable were adopted without change. In connection with the report on extra flexible 7 x 19 steel wire cable, Mr. Erickson pointed out that the Roebling cable of this denomination was made up of strands containing each three wires of different size. This resulted in extra strength, and the Roebling cable was considerably stronger than British cable of the same denomination having strands made up of equal wires. It was therefore decided to amend that part of the report relating to this matter to read as follows: "It is to be understood that the strand composing this cable must not necessarily be composed of wires all of the same diameter. With this change the report was adopted.

Mr. Birdsall asked whether it was not necessary to provide an elongation test of flexible cable. To this Mr. Manly replied that such a test was unnecessary as every cable before being put in place on an airplane was stretched to 50 per cent of its tensile strength.

There was no comment on the recommendation for cable reels, which consisted of a dimension diagram and a table. This was adopted.

Next the tachometer drive specification was taken up. It was pointed out that the design of this drive was one of the difficult problems of aircraft engine design. The report as it stood had been revised a number of times and represented much work. Major Vincent, in reply to a question, stated that as far as he knew the Signal Corps was satisfied with the design. It was pointed out that the members of the subcommittee had given the subject very careful attention and that it would be safe to pass the specification as submitted, which was done.

Rubber Hose for Gasoline

Next the specifications for rubber hose for gasoline were taken up. Mr. Tuttle of the Bureau of Standards, who read the report as printed, suggested a number of changes. Under the heading "Chemical Properties" it was specified in the original draft that "no organic matter other than para or plantation rubber shall be used in the preparation of this hose."

Considerable objection to this requirement developed, and he made an amendment that the passage be changed to read as follows: "If organic matter other than para or plantation rubber is used in the preparation of this hose, the amount and identity of such material shall be stated." Mr. Hale of the Goodyear Tire & Rubber Co. said that the rubber manufacturers asked that the first paragraph be eliminated. Concerning Mr. Tuttle's modification he said that the rubber companies would decline to give the ingredients of their product. He thought that the physical tests were very rigid and entirely protected the purchaser. Also, it was not within the province of the S. A. E. to require manufacturers to disclose what might be trade secrets with them. Mr. Tuttle replied that all of the physical tests described were made on new hose and did not bring out the durability of the prod-

Digitized by Google

uct. Mr. Hale said that in his opinion the physical tests were absolutely adequate. The specifications were based upon the practice of the Royal Aircraft Board of Great Britain and that board did not require the composition to be stated. All sorts of hose, including air hose, water hose and fire hose, were being sold on the strength of physical tests alone.

Another change suggested by Mr. Tuttle, based on recommendations made by manufacturers, was that the percentage of rubber in the hose be not less than 25, instead of 32 as called for in the original specifications. Mr. Crane suggested that the specifications of tubes of larger internal diameter than ¾-in. which "may be made from rubber sheet, in which case they must consist of at least two complete turns" were not sufficiently explicit, and, at his suggestion, the following was added to this paragraph: "And be formed into a complete tube in the further process of manufacture." With these changes the complete report was adopted.

The above was followed in the report by specifications of plain hexagon nuts, ball hexagon nuts, castle hexagon nuts, ball hexagon head bolts and plain hexagon head bolts. Mr. Ehrman, criticizing the manner in which the data regarding these parts were presented, recommended that the basic or nominal size be expressed in decimals of four figures and that all decimals in the tables which represented common fractions of an inch have the fraction added thereto in parenthesis.

Consider Threads of No. 12 Nuts

In connection with this subject, a rather warm discussion arose regarding the number of threads specified in No. 12 nuts. Grover Farnsworth of the Navy Aircraft Department wanted to know why 32 pitch was specified for these nuts, claiming that it was impossible to get dies and taps for this pitch. It appears that the former standard pitch for this size was 28. Mr. Ehrman denied that it was impossible to get the necessary tools for cutting these threads. He asserted that it was impossible to get quick delivery on gages for any of the common size screw threads. If better delivery could be obtained on gages for 12-28 threads it was due to the fact that this thread was in very little use and there was a comparatively small demand for gages of that size. According to Mr. Manly the subject was first taken up with the Signal Corps about a year ago.

The Curtiss Airplane Company at that time was using 12-32 screws in its JN model, and inasmuch as the government wanted quick production of this model, it was decided that no change should be made in the size of the thread used. Mr. Manly said that inasmuch as the 12-32 screw had already been adopted by the Society there remained nothing for them to do but to decide upon nuts that would fit these screws.

Mr. Hanks said that a committee should be appointed to confer with representatives of the Army and Navy and with the I. A. S. B. to clear up any little discrepancies which might arise. According to Mr. Erickson of the I. A. S. B., such a meeting is to be held at Washington on Friday at the new headquarters of the Board.

In the printed report were given tables and illustrations of turnbuckles, shackles, clip ends and clevis pins, and it was explained that these were put in merely for the purpose of giving the committee a chance to check them up for any typographical or similar errors, and that it was not necessary to take any official action on them. Specifications for airplane engine tests were adopted without change, as were the aeronautic engine testing form and the engine weight specification form.

Urge Longer Plug Threads

There was some opposition to the passage of the spark plug shell specification in the form presented. A letter had been received by the committee in which it was claimed that the length of thread was not sufficient to carry off the heat effectively. It was pointed out, however, that spark plugs with ⅝-in. length below the hexagon had now been the standard in automobile practice for two years, and more and more engineers were coming to use it. In further reply to the objection in the written communication it was stated that the heat dispersing capacity was much more a matter of thread fit than of thread length. Mr. Ehrman moved that the angle of the chamfer, which in the report was given as 35 deg. for the lower end and 30 deg. for the upper end, be made 35 deg. for both ends.

Mr. Birdsall advocated the use of a longer thread in view of the fact that spark plugs are now generally screwed into the cylinder wall instead of into the valve caps as formerly. If the spark plug has a long thread the water can be brought close to it, which is not the case if the thread is short. He related an experience where the shell of the plug had become discolored from the heat.

Mr. Manly said that there were not many 200 hp. engines in which the metal of the plug did not change in color when working under full load. This did not matter, as the ability of the plug to withstand high temperatures depended mainly upon the porcelain. The report was accepted with no other amendment than that regarding an equal chamfer of 35 deg. on both ends.

Next on the program was a table of bevel washers. Mr. Manly explained that these bevel washers had always been a source of considerable expense, as they generally involved a milling operation in their production. To reduce this expense it was decided to make them of rolled stock. It is not very practical to punch round washers from this rolled stock, and so Mr. Manly suggested that a series of square washers be added to the round washers, which could be readily produced from the rolled stock by sawing.

These bevel washers are to be made with angles of 6, 12, 24, and 36 deg., and by combining washers, a compound washer can be obtained approaching any desired angle within 3 deg. Besides being cheaper to make, the square washer permits of more accurate alignment of the bevel surface and the bolt. The adoption of this report without change concluded the work of the aeronautic section.

Motorcycle Division Report

William S. Harley, chairman of the Motorcycle Division, made the report of that division, which embodied recommendations regarding sixteen different items. The recommendations regarding the following subjects were adopted without change: Spark control, throttle control, kick starters, clutch pedal, brake pedal, chains, oil and grease cups, cylinder displacement, gearshift, carrying capacity, tires, headlamp mounting lugs and supporting prongs, spokes and nipple.

The recommendation regarding tires is that tires on military motorcycles, rear and side cars shall be of a clincher type, 28 x 3 in. Mr. Wolfe of the Goodyear Tire & Rubber Co. suggested that this be amended to read: "Of the clincher type and fitting a 28 x 3-in. rim." This would take care of over-sized tires, 29 x 3½ in. in dimensions, which are now being used to quite an extent on military motorcycles. Mr. Harley, however, said that these tires were entirely unsuited to motorcycles as now built owing to the fact that there was not sufficient clearance for the tires in the frame, and the division had gone on record as favoring the 28 x 3 in. size. No change was made in the recommendation.

Change Magneto Dimensions

In connection with the magneto dimensions specifications, Mr. Libby of the Splitdorf Electrical Co. recommended that the length of magneto space (from large end of shaft taper) be made 6⅜ instead of 6⅛ in. as recommended, and the width of the magneto space 3¾ instead of 3⅛ in. If the space allowed were smaller than that, it would not accommodate the Splitdorf magneto. This suggestion was accepted and the specifications were then adopted.

Mr. Ehrman pointed out a number of errors in the drawing of the fuel and lubrication pipe fittings and he also recommended that in addition to the dimensions given on the drawing, the root diameter limits of both the male and female threads be inserted. An amendment to this effect was carried and the recommendation was then adopted. It was found that the nipple head depression in the wheel rim as specified was covered by a patent, and inasmuch as it is the invariable rule of the S. A. E. not to standardize any patented article,

Westinghouse Cam Regulated Generator

Designed Specially for Truck Work—Voltage Regulated by a Vibrator Cutting Field Resistance In and Out—Vibrator Is Under Both Magnetic and Mechanical Influences

A CAM-REGULATED generator has been brought out by the Westinghouse Electric & Mfg. Co. for use particularly on army trucks and high-grade commercial vehicles. It is designed to meet all the requirements of the government's specifications for army truck equipment as approved by the Quartermaster General in May, 1917. The generator is being produced at the Shadyside Works of the Pittsburgh concern.

The machines are ordinarily adjusted at the factory to give a voltage not greater than 8 volts at 1 amp. output at speeds up to 2000 r.p.m., and with a load of 15 amp. to give a voltage not less than 7 volts up to 2000 r.p.m. The generator is capable of giving a continuous output of 12 amp. at 7.5 volts, and the range of possible adjustment of the regulator makes it also applicable to some of the higher class passenger or general utility vehicles as well as military trucks.

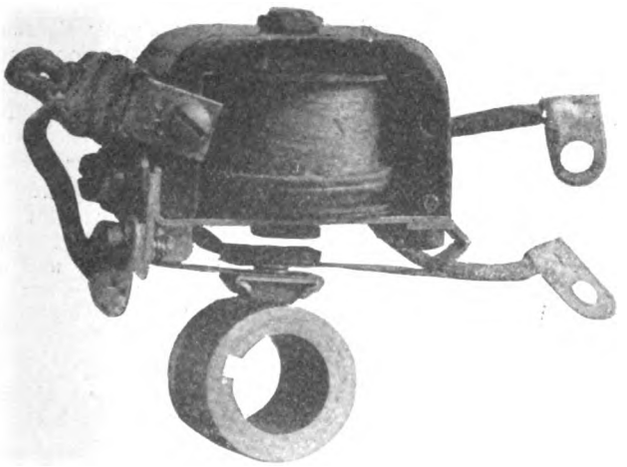

Fig. 1—Regulator unit of the Westinghouse cam-regulated generator

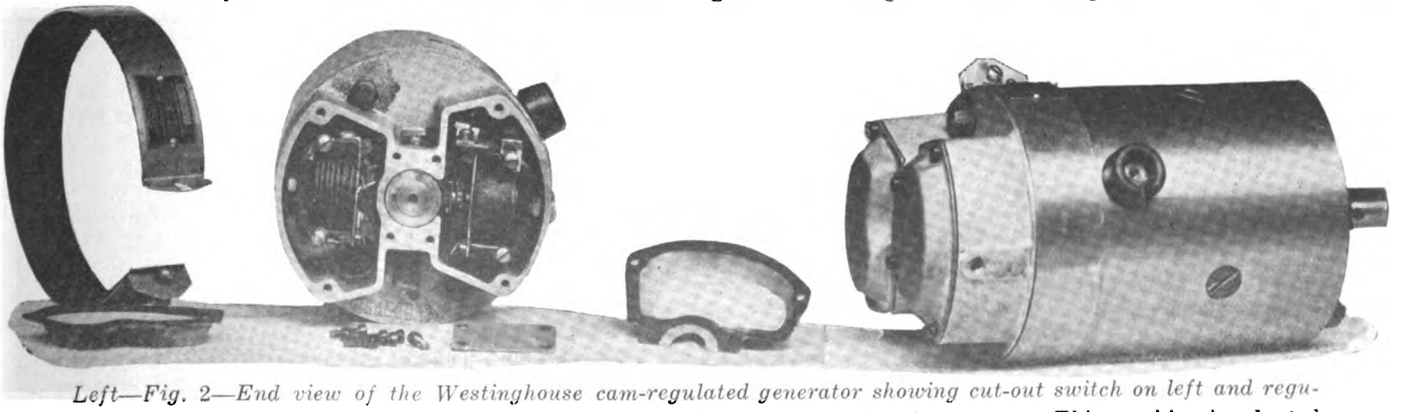

In appearance the generator is similar to other machines of Westinghouse manufacture, with the frame made from steel pipe having a circular section that lends itself to cradle mounting on the engine. The end brackets may be extended to form flanges for end mounting, in which case the cradle brackets are not required. The construction of the armature shaft and regulated generator parts is along conventional lines. Ball bearings are used for the coupled type, while, where the generators are mounted on the gear cases by supporting flanges, large bronze sleeve bearings are employed. These latter are lubricated by a constant stream of oil. The windings are mechanically and electrically strengthened by a double impregnating treatment, making them oil and water proof. Four brushes are supplied on the generator in place of the customary two, and the field coils are securely located on poles and highly insulated from ground. It requires but one wire to connect the generator to the car's wiring system.

It is in the cut-out switch and voltage regulator that the instrument differs from other types. The cut-out and regulating units are mounted within the bracket on the commutator end, and removable covers provide access to both. The cut-out is adjusted to close the circuit to the battery when the speed of the generator has reached such a point as to give 6.5 volts at the generator terminals; it opens with a reverse current of 1 amp. and at a speed below the cut-in speed to avoid any tendency to chatter when the generator is running near the cut-in speed. The cut-in speed varies from 5 to 10 m.p.h., depending on the gear ratio and wheel diameter used on the car.

Regulator Specially Developed

The regulator has been especially developed for truck work. Movement of one of the contacts of the regulator is caused by a cam on the generator shaft so that this operation is positive and contacts are either in intimate contact or entirely open. A slight wiping motion keeps the contact surfaces clean. Regulation is effected by opening and closing of the regulator contacts, thus cutting in and out a resistance connected across these contacts and in series with the field winding of the generator; the time the contacts are closed varies with the speed. The generator will maintain a proper voltage and current output even if the battery becomes disconnected. An opening in the end bracket affords access to the regulator adjusting screw.

The action of the regulator is explained in Fig. 1. The contact affixed to the armature moves back and forth with the latter to and from the end of the armature core as the amount of flux through this core varies. Since this flux varies with the voltage of the generator, the position of the surface of the top contact is at all times determined by the generator voltage. If this voltage tends to rise, the top

Left—Fig. 2—End view of the Westinghouse cam-regulated generator showing cut-out switch on left and regulator on right. Right—Fig. 3—Exterior of the Westinghouse cam-regulated generator. This machine is adapted to cradle mounting

Digitized by Google

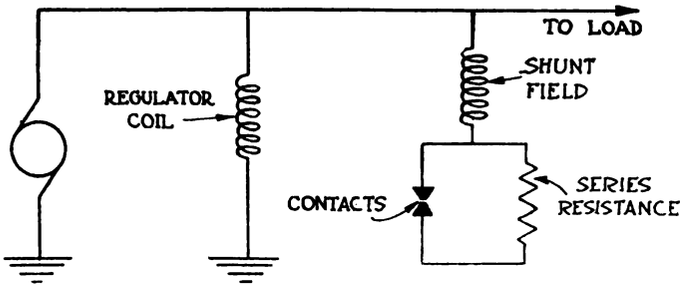

Fig. 4—Approximate wiring diagram of the Westinghouse cam-regulated generator

contact will then be withdrawn from the lower contact.

Since the lower contact is always moving up and down under the influence of the cam, the duration of contact in each revolution will be proportional to the position of the top contact, which in turn is proportional to the voltage. Thus, if the voltage tends to increase the top contact will be withdrawn from its mean position, while if the voltage tends to decrease, due perhaps to lower speed or increased load upon the generator, the upper contact will approach the lower and thus make the duration of contact longer in each revolution. Since the two contacts short-circuit a resistance in series with the shunt field of the generator, the operation is identically that of the familiar Tirrell regulator used in power plants.

Adjustment is made by bending the brass piece at the outer end of the steel frame. By straightening out the crooks in it the armature is moved farther away from the core, and this increases the regulated voltage. By squeezing up the brass piece the armature is allowed to move up nearer the core. This gives the core a greater influence on it and tends to take it away from the contact, thus increasing the length of time during each revolution in which the fields regulating resistance is left in the circuit.

Standards Committee in Busy Session

(*Continued from page* 138)

it was decided to eliminate the dimensions .216" R and 0.180" which overcame the difficulty. On the suggestion of Mr. Wolfe, the minus tolerance of the circumference of the rim was changed from 11/64 to 9/64 in., this change having been decided upon by the Clincher Tire Manufacturers Association. With these changes the wheel and rim specifications were adopted.

Mr. Harley stated that the division had also decided upon an 18 mm. spark plug, having been given to understand that this was the size of plug to be used in the Liberty motor truck engines. As the motorcycles will be used largely in conjunction with the trucks, it was considered advantageous to have the same size of plugs in use on both types of vehicles. Since that time, however, it was learned that the ⅞-18 plug would be used on the truck and the action regarding the use of the millimeter plug on motorcycles was rescinded.

The newly appointed roller chain division made its first report, containing recommendations regarding the nomenclature of roller chain parts and a table of roller chain dimensions. The chain sizes recommended were selected from the most generally used existing series, with the addition of a 2½-in. pitch for heavier duty. This series was chosen in order to provide the best practice during the existing war conditions. Other series will be worked out for light duty at high speeds, and heavy duty at slow speeds, and will be influenced more or less by the introduction of alloy steels in future chain manufacture. The chain size numbers indicate the number of quarter inches in the pitch. The report was adopted.

Tractor Division Report

Chairman Parrett of the Tractor Division read the report of that division as formulated at a meeting on the previous day. It was accepted as presented. In the report of the data sheet division it was stated that a new comprehensive index to the data sheets had been prepared and sent out to the members. Suggestions were made that a number of obsolete sheets be eliminated and that several other sheets be revised. This report was adopted.

Miscellaneous Division Report

In the printed report presented to members of the meeting were given complete tables of yoke and eye rod ends, plain rod ends and eye rod ends. Only the two largest sizes in each of these tables, ⅞ in. and 1 in., were new, and the addition of these sizes to the existing standards was decided upon. The subject of bumpers and mounting had been given consideration by the miscellaneous division in co-operation with the Bumper Manufacturers Association and after a careful review of the proper height for both front and rear bumpers, for various conditions of loading, fender clearance and collision, the following heights and dimensions were recommended. The committee also believes that there is a chance for further work along the line of methods of attaching the bumpers.

Table of Standard Bumper Heights and Dimensions

	Front	Rear
Height from center of face to ground	21	22
Over-all length	Between 59 and 60	Between 59 and 60
Bumper face	Flat	Flat
Vertical depth bumper bar min.....	2	2½

Dimensions in inches.

The final item in the report of the miscellaneous division was a table of S. A. E. screw threads, containing both the regular S. A. E. and the new S. A. E. fine thread. A diagram showing the pitches corresponding to various diameters of the new fine thread was given in the report of the recent standards committee Washington meeting in AUTOMOTIVE INDUSTRIES. All of the items in the miscellaneous division of report were tables to pass upon.

Marine Division Report

The Marine division presented reports on steel engine couplings, steel reverse couplings, cast iron reverse couplings, shaft couplings and propeller mounts. These were in the form of tables with dimension drawings. The steel couplings called for taper fittings and determined opposition was made to the adoption of this form of fitting by a manufacturer of flexible couplings, who said that the adoption of this sort of fitting as standard would be detrimental to his business, as his coupling could not be fitted to a tapered shaft end.

There was considerable discussion on this point, but inasmuch as it was getting late and there were only a few members of the Standards Committee left in the room, it was found that there was no quorum present, and that no action could be taken on the report. A vote was taken and showed it to be the sense of the committee that with a number of corrections of typographical errors, the report should be adopted as presented. Mr. Smith, who objected to the adoption of a standard for couplings with tapered fittings, will be given a chance to present his views to the Marine Engine Division at one of its next meetings.

There will be a general marine engineering meeting under S. A. E. auspices in this city on Jan. 25, and it is possible that the Marine Division of the Standards Committee will have a meeting at that time. All of the subjects on the program having been passed upon, the meeting adjourned.

Digitized by Google

Standards Division Meeting

A MEETING of the Tractor Division was held at S. A. E. headquarters on Tuesday. Of the members of the Division, Chairman Dent Parrett and Joseph Van Blerck were in attendance, and Standards Manager M. W. Hanks and P. M. Heldt of *Automotive Industries* were also present. The recommendations formulated at the Minneapolis meeting were gone over in detail. In regard to the suggestion that tractor rims be cut in lengths of 12, 14, 16, 18, 20, 22 and 24 ft., it was pointed out that this resulted in rather large steps (about 7¾ in.) between diameters of successive sizes of wheels. It was decided to compose a letter explaining that it is not the intention of the Standards Committee that tractor manufacturers should change the wheels on their existing models, but that, whenever they are developing a new model they should aim to adopt one of the suggested dimensions. The letter is to be sent to all manufacturers of tractors, who will be asked to criticise the recommendations and to make suggestions in case they cannot adopt them in their practice.

Slight Change in Wording of Specification Blank

A slight change in the wording of the short specification blank, already adopted by the Division, was decided upon, this being to the effect that the speed which is normally used in plowing is to be indicated by a check mark, the word "normally" not being used in the original recommendation.

In connection with the recommendation that a pad of magnetic insulating material at least ½-in. thick be placed under magnetos when mounted on cast iron brackets, a letter had been received by Chairman Dent Parrett from a magneto manufacturer protesting against this recommendation. The manufacturer in question asserted that with many makes of magnetos this pad was unnecessary, and the requirement would be a hardship on tractor manufacturers. Chairman Parrett reported that he had replied to this letter by stating that the recommendation was adopted at a meeting of the tractor division held in Chicago, which was attended by representatives of practically all the magneto manufacturers, and there was no opposition to it. It was decided to report the substance of the letter and of Mr. Parrett's reply to the Standards Committee.

The recommendation regarding tube size for gasoline and oil leads was ratified, though there was a feeling among the members present that an additional, larger size would be necessary for the heavier tractors.

Drawbar Connections

Considerable discussion developed in regard to the proposed draw bar connections. Under this heading specifications are given of the size of stock from which the coupling is to be made, the width of the space for the draw bar, the size of hole for the draw bar pin, and the position of this hole. A drawing accompanies this specification, which contains full dimensions for the coupling. Mr. Van Blerck urged that no dimensions should be given except the width of the space for the drawbar, the size of the hole and the location of same, so as to afford manufacturers and designers a chance of working out the details of the coupling according to their own best judgment. Other members present felt, however, that the design shown in the sketch would be suggestive to engineers, and after a full discussion of the subject it was decided to caption the cut "Suggested Design of Drawbar Coupling."

Electric Vehicle Report

A meeting was also held by the Electric Vehicle Division and the following recommendations were made:

It is recommended that the matter be laid before the different members of the Committee as to whether it is the consensus of opinion that an attempt be made to standardize a specification for .motor rating. Mr. Queeney stated that there already is a specification for railway motor practice, and that a specification along similar lines would be helpful. He promised to procure a copy of the railway motor specification and send it to Mr. Hanks, so that all the members of the Division might be supplied with a copy. This railway motor specification will serve as a model for a type of specification for electric vehicle motors.

This Division was requested to standardize the focal length of headlamp bulbs for electric vehicles along the same lines as already done for gas cars, if this be possible. This matter was referred to the Lighting Division and they recommended the standard focal length of 1¼" for both electric and gasoline propelled vehicles.

Standardization of Battery Compartment

Mr. Hanks was instructed to bring up at the Standards Committee meeting the question of whether or not the 1¼" focal length applies to all bulb sizes. If it does apply to all sizes, it should be so stated, and if it does not, the limits should be specified.

Mr. Ford referred to a letter he had received from W. P. Stone & Co., South Boston, Mass., suggesting that their interchangeable battery compartment be standardized. The fact that this battery compartment is patented prevents any action whatever upon this specific type. The subject of compartment sizes is now before the Division.

Mr. Hertner submitted copies of correspondence from representatives of the manufacturers of electric passenger cars. The consensus of opinion is that the battery compartment is so closely allied to the body line of passenger cars that no standard can be adopted which will apply to existing vehicles; if, however, some standard sizes could be worked up, they might be applicable for future designs. It was suggested that the manufacturers agree upon the specific sizes for future use.

Commercial Car Problem

Mr. Whitney, as Chairman of the Standardization Committee of the Electric Vehicle Section of the National Electric Light Association, reported that a Sub-committee had been diligently attacking the problem of commercial cars, and it was his opinion that some results of their work were available. He promised to obtain whatever data and conclusions this Sub-Committee had arrived at and submit them to the Division for action.

This Division had been given to understand that the tire people must be convinced of the merits of the present Whitney test, or the Whitney test must be revised so that it would be satisfactory to the tire people. Several truck manufacturers are buying tires based upon the Whitney method of testing. The matter was put before the Standards Committee once before and was acted upon unfavorably, due to the attitude taken by the tire manufacturers. The only reason that this subject has been in the hands of the Electric Vehicle Division is that the electric vehicle manufacturers have been more interested in obtaining solid tires of high efficiency. With the high cost of gasoline, tire efficiency is becoming more important to manufacturers of gas cars, and perhaps the time is ripe when the subject is of enough general interest for it to be put before the Standards Committee again.

Letter from A. I. E. E.

Mr. Hanks read a letter received January 7 from the American Institute of Electrical Engineers, stating that the A. I. E. E. had no standard specification for electric vehicle cable and that their only cable standards were those on pages 68 to 76 inclusive of the standardization rules. Table XIII on page 71 is probably the best suited. This gives the number of strands and wire sizes for different sized cable. It was suggested that information based upon this table be obtained to show what kind of insulations are being used in regular practice. Recommendations for standardization will then be based upon this information.

The Miscellaneous Division, of which Mr. Ehrman is chairman, extended the table of rod end pins to include pins for ⅞-in. and 1-in. rods.

Latest News of the

Kettering President of S. A. E.

Beecroft First Vice-president —Hinkley, Houston, Glover, Sutphen and Brate Vice-presidents

NEW YORK, Jan. 10—Chas. F. Kettering, vice-president of the Dayton Engineering Laboratories Co., is the president-elect of the Society of Automotive Engineers.

Kettering has been connected with the Dayton Engineering Laboratories Co. since 1909. Prior to that he was engineer in charge of development work on electric apparatus for the National Cash Register Co. He was graduated from Ohio State University in 1904.

David Beecroft, who is directing editor of the Class Journal Co., and has been active in society affairs for a number of years, is first vice-president. The complete slate follows:

President—Chas. F Kettering, vice-president Dayton Engineering Laboratories Co.

First vice-president—David Beecroft, directing editor Class Journal Co.

Second vice-president—C. C. Hinkley, president and general manager Hinkley Motors Corp, representing motor car enginering.

Second vice-president—Geo. H. Houston, representing aviation engineering.

Second vice-president—Fred Glover, Emerson-Brantingham Co., representing tractor engineering.

Second vice-president—Henry R. Sutphen, vice-president Submarine Boat Corp., representing marine engineering.

Second vice-president—H. R. Brate, representing stationary internal combustion engineering.

Secretary-General Manager — Coker F. Clarkson.

Treasurer—Chas. B. Whittelsey, vice-president Hartford Rubber Works.

Councillors 1918

B. B. Bachman, engineer Autocar Co., Ardmore.

H. L. Horning, engineer Waukesha Motor Co., Waukesha, and chairman Automotive Section of the War Industries Board.

C. W. McKinley, chief engineer, Willys-Overland Co.

George W. Dunham, past president.

Russell Huff, past president.

Councillors 1919

Chas. S. Crawford, chief engineer Premier Motor Corp.

Chas. M. Manly, vice-president and chief engineer, Curtiss Aeroplane Co.

J. V. Whitbeck, chief engineer, Chandler Motor Car Co.

—

To Have Gasoline Administrator

WASHINGTON, Jan. 10—In addition to the administrators of food and fuel there is now to be an administrator of oil and gasoline. He will operate under Director Garfield of the fuel administration. His name has not been made public, but it is said he will not be connected with any of the large companies. A. C. Bedford of the Standard Oil Co. has thus far acted as chairman of the Petroleum War Service Committee.

During the early stages of control the oil industry will be allowed to continue on its present basis without interference that would not be supported by full information on its position. The initial stages of control will deal almost exclusively with the problems of facilitating distribution and promoting conservation measures. The immediate task which will confront the administration will be the perfection of an organization adequate to handling the complex phrases of the industry which must be dealt with.

M. A. M. A. Re-elects Officers

NEW YORK, Jan. 9—The Motor & Accessory Manufacturers' Association to-day held its annual meeting and re-elected four retiring directors: Christian Girl, Standard Parts Co., Cleveland; E. H. Broadwell, Fisk Rubber Co., Chicopee Falls, Mass.; E. W. Beach, Manufacturers' Foundry Co., Waterbury, Conn.; L. M. Wainwright, Diamond Chain & Mfg. Co.

All of the officers of the association except the secretary were re-elected as follows: President, C. W. Stiger, Stromberg Motor Devices Co., Chicago; 1st vice-president, C. E. Thompson, Steel Products Co., Cleveland; 2nd vice-president, E. H. Broadwell, Fisk Rubber Co., Chicopee Falls, Mass; 3rd vice-president, T. J. Wetzel, Precision Die & Casting Co.; treasurer, L. M. Wainwright, Diamond Chain & Mfg. Co.; assistant treasurer and secretary, W. O. Rutherford, B. F. Goodrich Co. Mr. Sloan, formerly assistant treasurer, remains a member of the board of directors.

500 Attend M. A. M. A. Banquet

NEW YORK CITY, Jan. 9—The fourteenth annual banquet of the Motor & Accessory Manufacturers' Assn. held at the Waldorf to-night was attended by over 500 members of the association and guests. After an address of welcome by President Chas. W. Stiger, a combined dinner, vaudeville performance, war lecture, and war movie show took place, and continued until 1:30 a. m. The war talk by Corp. R. Derby Holmes of Boston, and late of an English regiment, was one of the most interesting war talks of the season. This was followed by five reels of Italian war films showing the Italian army fighting in the region of snows and ice, and also the work of the Italian motorboat submarine chasers, dirigibles and airplanes.

Show Hits Old-Time Stride

Weather and Rumors Make First Days Small—Good Net Already—Result Seems Assured

NEW YORK, Jan. 9—The New York show hit its old-time stride to-day after a rather bad beginning. The first day, Saturday, was the end of the coldest spell New York has ever had. People were still sticking close indoors and rumors were afloat that Grand Central Palace was cold.

Monday the people had not fully awakened to the fact that the show was on as big as ever, but by Tuesday, with the newspapers carrying advertising and their usual show stories and the hotels packed to the roofs with automobile people, the city waked up and the city flocked out to supplement the big army of out-of-town people who began to arrive in force.

To-day, Wednesday, the old-time show has "come back." The attendance is as big as last year if not bigger, and the management estimates that if the relapse of the first few days should prove only to be a delayed attendance the last few days might be bigger than ever before.

High-priced Cars Sell Well

Business also is beginning to pick up, and among the high-priced cars, too. Stutz, McFarlan, National, Pierce-Arrow, Packard, Franklin and Marmon report a strong business tone, and Auburn, which looks more to the West than to the East for business, said it felt greatly encouraged with the response it was meeting. Paige reported a good business.

On the accessory floors the feeling of optimism is supreme. People are said to be purchasing heavily, especially of the smaller articles, such as car locks, lenses and other easily carried articles. Ford devices sell in volume.

At the dealer dinners that are being held business experts are showing the dealers why business is bound to be good. The end of the week should see a wonderful stiffening of the backbones of some who came to the show expecting to see an exhibition of gloom and impending disaster, which they have not found.

Jobbers are here in numbers, looking for goods to supply the biggest demand they believe they have ever been able to foresee.

Automotive Industries

No G. M.-Chevrolet Merger Yet

Concerns Maintain Their Relative Independence at Least for Time Being — Declare 3% Dividend

NEW YORK CITY, Jan. 9—Plans for merging the Chevrolet and General Motors companies were again pigeon-holed after a joint directors' meeting yesterday. Wall Street had freely predicted that such a merger would take place, and it had been accepted generally as an almost foregone conclusion that yesterday's meeting would see the deal through. It is very possibly due directly to General Motors war business in trucks, shells and Liberty airplane engines said to total $60,000,000 during 1918 that the deal did not go through.

Both companies have declared a 3 per cent dividend to stockholders as of Jan. 18, the dividend being payable Feb. 1. This is a regular dividend and was simply a matter of form as far as the meeting was concerned, as the directors of the General Motors Co. declared the dividend and then adjourned, after which the directors of the Chevrolet company held their meeting. Directors of both companies stated that there is no immediate intention to consolidate.

—

Central Warehouses for Airplane Repair

INDIANAPOLIS, Jan. 6—A $600,000 airplane warehouse is being erected here for the repair of all army airplanes located east of the Mississippi and north of the Ohio River. The building for body repair is 241 x 264, and the motor repair building is 239 x 294. Four large barracks are to be built to house 25 officers and 700 enlisted men in charge of the airplane work.

—

Curtiss Output 12-15 Planes Daily

BUFFALO, Jan. 8—Curtiss Aeroplane & Motors Corp. is turning out from 12 to 15 machines daily, and is preparing to increase this output in 1918. The volume of shipments for the last six weeks has been about $3,000,000. It is estimated that by March the monthly turnover will be $5,000,000.

—

Wright-Martin Profit $1,000,000

NEW YORK, Jan. 8—It is estimated that the Government contract with the Wright-Martin Aircraft Corp. for 550 Hispano-Suiza motors at $5,000 each will yield $1,000,000 profit, or the equivalent of $1 a share on the company's outstanding common stock. About 200 of the engines have been shipped already and the remaining 350 are ready for shipping instructions. The problem of changing the production from 150 hp. to 220 hp. engine was accomplished without great cost or confusion, and work has already been started on the latest Government order for 4000 Hispano-Suiza motors and parts, making the equivalent of 5500 engines. This contract involves $28,000,000.

—

Aircraft Inspectors Band Together

DETROIT, Jan. 5—The Detroit Aircraft Inspectors club, composed of the engineers who construct and inspect airplanes in this city, has been organized for more complete co-operation in the work of the members. Captain James Haeslett, who has charge of the Government aircraft equipment in the city, and Captain Hotchkiss of the Washington division of aircraft equipment addressed the members. The officers elected follow: President, Lieutenant E. T. Jones; vice-president, George Gray; secretary-treasurer, A. T. Davidson. Monthly meetings are scheduled. It is stated that the first of the Detroit built war planes was successfully demonstrated during the past week.

—

Coal Still Short in Detroit

DETROIT, Jan. 5—The coal situation still occupies the center of the stage, and receipts have dropped off in the last week. Last week something over 500 carloads were received, but this week only about 150 carloads arrived. Manufacturing plants are still running with limited supplies, and relief is looked for through Government control of the railroads. Flint, Jackson and Lansing are possibly in even worse condition, and two Lansing factories will have to close this week if coal does not arrive.

—

Canada Sees Trouble Ahead

MONTREAL, Jan. 5—It having been reported throughout the trade in Canada that the Government proposes to restrict the importation of gasoline and motor cars, the automobile dealers are planning to lay facts before the Government to prove that such action would be harmful to the dominion. The Montreal Automobile Trade Association through its manager, T. B. Kirby, is gathering information and it is probable that a meeting of the trade will be held at an early date.

—

Furniture Men Making Airplane Parts

GRAND RAPIDS, Jan. 3—The Bissell Carpet Sweeper Co. is working on a large war contract for airplane parts, which will extend through a long period. This is but one of many received by Grand Rapids furniture manufacturers.

N. A. C. C. Reports Record Shipments

Deliveries Exceed Any Previous Year — Production Slowed by Material Shortage

NEW YORK CITY, Jan. 9—The total shipments of automobiles by members of the National Automobile Chamber of Commerce and by the country in general, for 1917 greatly exceeded the shipments of 1916 or any other previous year in the history of the industry. Taken month by month the shipments during 1917 exceeded those of the previous year with the possible exception of December. There was no slowing up on production until a shortage of materials arose in October, and during October, November and December production figures fell below those of the corresponding months of 1916.

According to reports from the regular monthly meeting of the directors of the National Automobile Chamber of Commerce held to-day the automobile manufacturers have been playing their part in relieving railroads of automobile shipments, because there has been a substantial falling off in shipments during the past few months due to the increased driveaways from factories.

Several factories in the Great Lakes zone, which may be said to include Cleveland, Toledo, Detroit, Pontiac, Flint, Lansing and adjacent places, are driving away a large percentage of cars produced. One distributer in the Southeast drove away over 1000 cars during the month of November.

Some of the large New York distributers are now arranging to drive all of their cars to Buffalo, where they will be stored. Other manufacturers are arranging similar plans to relieve the railroads during the coming months and through the Spring. It is hoped road conditions will not interfere with the plans.

At to-day's meeting, Chairman A. W. Copland, of the Automobile Industries Committee, and Hugh Chalmers, of the same committee, reported at length on the work of the committee in Washington and on its co-operation with the War Industries Board. The committee has done commendable work by way of placing or arranging for Government work other than automobile manufacture with many factories that are slack.

Roy D. Chapin, chairman of the Highways Transport Committee, and Windsor T. White, president of the White Co., reported on the truck conference held yesterday.

Digitized by Google

The Platform on Which the N. A. C. C. Truck Makers Stand

1—RESOLVED, *That the motor truck manufacturers of the United States, in convention assembled in New York on January 8, 1918, hereby tender to the President of the United States, to the Secretary of War and to the Council of National Defense, their services and co-operation in meeting the transportation needs of the Government and the country, and offer the facilities of their factories to aid in the prosecution of hostilities against the Governments of countries with which the United States is at war. It is resolved, That copies of this resolution be addressed to the President and the Secretary of War.*

2—WHEREAS *the present unprecedented crisis in the railroad transportation service of the country has made imperative an extraordinary development of motor trucking by highway to meet the needs of the War Department of the Government and of the industry and commerce of the United States, and*

WHEREAS *it is essential to the effective use of motor vehicles as a measure of relief of freight and express congestion that the main highways be put and kept in good usable condition for the movement of the products of farm and factory, it is*

RESOLVED, *That the Director-General of the Railroads be urged to raise the embargo against the use of open-top railroad cars for the shipment of road materials and machinery in sufficient time to permit of resumption of highway construction and repair early next spring in the northern states and, if conditions permit, that this portion of the order be rescinded this winter in so far as it affects the Southern States and California.*

3—RESOLVED, *That a committee of five representatives of motor truck manufacturing companies be appointed by the president of the National Automobile Chamber of Commerce to co-operate with and assist the Highways Transport Committee of the Council of National Defense in working out problems arising in connection with the organization and development of transportation by public highway for the relief of railroad freight congestion and to facilitate the movement of military trucks and the transportation of the mails.*

4—RESOLVED, *That the representatives of motor truck companies in attendance at this convention indorse unanimously the work and plans of the Highway Transport Committee of the Council of National Defense and hereby tender the full co-operation of the motor truck industry in developing ways and means for increasing the effectiveness of the motor truck in moving merchandise and other freight and express matter.*

5—RESOLVED, *That the motor truck manufacturers of the United States, assembled in convention January 8, 1918, who view with increasing apprehension the various forms of drastic motor truck legislation already passed and other forms threatened, hereby appeal to the Council of National Defense, asking the council to request the various states in this time of stress when transportation is the need of the hour, to refrain from passing or enforcing any unreasonable legislation that would interfere with motor truck transportation.*

Motor Trucks Will Help Win the War

N. A. C. C. Urges Necessity of Truck Makers and Users Co-operating with the Government—Must Help Relieve Railroads

NEW YORK, Jan. 8—"The automobile industry is more interested in having democracy as usual after the war than business as usual now." This was the stirring remark of Hugh Chalmers made at the Motor Truck Manufacturers' Convention being held in the boardroom of the N. A. C. C. H. L. Horning, Automotive Section of the War Industries Board, said: "The truck has now come to the point of being a national necessity." About 100 of the most prominent truck makers of the country were present.

The keynote of the meeting was service to the Government. This service was expressed in co-operating with the Government motor truck program; in assisting to relieve the railroad congestion by the use of motor trucks and the additional service of the motor truck industry so that manufacturers may better understand the demands to be made upon them and be better prepared to meet them.

He spoke of the new kind of slackers which we have among us and who are not only those who refrain from going to war. He mentioned particularly people who complain about the absence of parlor cars and smokers on railroad trains and concluded by stating that these men were just as much slackers in preventing the full co-operation of our citizens toward winning the war as those who unfairly seek to evade the draft law.

George M. Graham, assistant commercial manager of the Pierce-Arrow Motor Car Co., Buffalo, N. Y., briefly outlined the work which the motor truck industry has already rendered to the Government. He told of the work which motor trucks did on the border with General Pershing's expeditionary force in Mexico, and traced the industry's work from that time up and including the many weeks of effort of the best brains of the motor truck industry in the development of our standardized trucks.

Truck Transport Necessary

The great problem now before the motor truck industry is to prove the feasibility and practicability of employing the motor truck to relieve the acute railroad congestion which is bound to increase as our rolling stock wears out through lack of proper care and as our Government's preparation increases to keep our army of one million men supplied 3000 miles from their base.

Major Edward Orton, Jr., Q. M. C. U. S. A., told of a great work which the Government is now doing in driving its standardized war trucks and other trucks still being shipped on previous orders overland from their points of assembly to the seaboard. He pointed out that the most important effects of these overland drive-aways of war trucks are not in the 15,000 freight cars saved for other needs or for the 100,000 tons of freight which they will carry, but instead are the great educational value which these long convoys of trucks will have upon the people of America to make them wake up to the fact that we are really at war.

These trucks will be the first physical contact which a large proportion of our citizenship has had with the materials of the war. We have not yet been bombed by enemy airplanes, nor have our coasts been shelled by the guns of great dreadnoughts lying out of sight of our coast behind the horizon. These war trucks will be one of the first object lessons of the war and of the great preparations which our officials in Washington are making to assure a victory for our arms.

The second great benefit of these drive-aways will be the bringing to the citizenship of the great necessity for overland motor routes and roadways capable of withstanding motor truck traffic and of roads which actually lead somewhere, and do not branch out to obscure points as had been caused by the individual road-building programs of our several states. This need has long been

Digitized by Google

in existence, but it will be the lesson taught by these war trucks that will bring it to the fore and result in the great development of our national highways. These great drive-aways of our 30,000 or more war trucks will have a bigger immediate military advantage than a commercial one. This will be in the training of the great personnel of truck drivers, truck masters and mechanicians required to keep our trucks in motion.

He briefly outlined the many months of study which were necessary before the first drive-away was successfully accomplished. He told of how engineering reports on the roads had to be secured; how routes had to be selected; how road maps had to be secured from the topographical departments of the several states through which the route led; of building gaps in the proposed road; of repairing such parts of roads selected as were impassable for trucks; of the cooperation which had to be expressed by the state highway departments of the various states to keep the route clear of snow during the winter months and of the necessity of supplying doctors, kitchen equipment, oil-filling stations along the route, sleeping quarters and a plotting of the various truck assembly plants and their relation to the main cross-country route.

Properly Handling Freight

He also told of the great detail work which had to be successfully completed in getting the freight which the trucks will carry to the proper points so that it might be loaded into the trucks. It was also necessary to see that this freight was of the proper kind, size and nature that it could be economically loaded into the prescribed motor truck bodies.

He then told briefly of the plans of the Government for training the drivers of these trucks. He mentioned the possibility of seriously damaging the trucks if run overland by green or inexperienced drivers, and was of the opinion that the Government's eventual policy would be to have a green crew act as observers along with a trained crew on one trip and then to let the green crew take out a new fleet on the second trip. In this way he pointed out that the trucks would be much less liable to be damaged while under the eye of an experienced driver on the seat of each vehicle with the novice. At the present time the personnel for only twelve motor truck companies of thirty-three trucks each had been drafted from the various cantonments for the work. Undoubtedly others will be selected as soon as the standardized war trucks begin coming through in quantity.

David S. Ludlum, president of the Autocar Co., Ardmore, Pa., spoke of the positive necessity of establishing schools where motor truck drivers could be trained instead of trying to give them training for a few hundred miles in the overland drive-aways. He brought out the fact that the great purchase of motor trucks would mount into millions of dollars and that it would be folly to entrust this vast investment to the hands of unskilled men who might abuse the trucks by their inexperience.

He also spoke of the fatality of one of the truck drivers on the Packard train which left Detroit Dec. 14 and arrived at Baltimore Dec. 28. Although one of the rules which every army truck driver must learn is that he must bring his truck to a stop before crossing a railroad track to see if the way is clear, one of the truck drivers was struck by a locomotive on the trip while passing through Warren, Ohio. The truck driver was killed and the truck demolished. Mr. Ludlum brought out the fact that this accident occurred at 2 a. m. and was of the opinion that no night driving should be permitted on the overland drive-aways unless each driver had received a sufficient amount of actual road driving previously. Even then he thought that 10 hours continuous driving was all that should be required of the new drivers now.

Hugh Chalmers made a great appeal for a better understanding of what the war really means to the automobile and motor truck industry. He briefly sketched the work of the automobile industry committee in Washington and how it was partially instrumental in blocking the proposed curtailment of the automobile industry because of the misinformed assumption that it was a non-essential. He stated that there would be no official curtailment of the motor car industry except in so far as the question of materials arose.

Several Shocks to Come

He stated that the citizens of the United States will have to meet several great shocks in the near future. The automobile industry will have to meet these shocks as well as the other great industries of the nation. He told of a recent movement in Washington to cancel the New York and Chicago National Automobile shows in order to save railroad transportation and coal with which to heat the show buildings. It was partially due to the work of his committee that these movements were sidetracked. He pointed out that of all years in the history of the automobile industry 1918 was the one year in which the shows should be continued, in order that the necessary readjustment between the passenger car maker, his distributer and his dealer might be effectively met and that the calling off of the shows at this time would entail a great financial loss of thousands of dollars due to previously arranged contracts and preparations.

He also spoke of the possibility of closing down all the schools and churches in this country for a period of one week. In this connection he said it was also possible that all of the industries might have to shut down completely for one week, including those of the automobile and motor truck, in order to relieve the acute railroad congestion and start off anew under better conditions at the end of the shutdown. He gave it as his opinion that he would rather shut down completely for one week than to run at the present inefficiency with the almost positive assurance that the efficiency of the plants would be further decreased unless the present railroad congestion was immediately removed.

H. L. Horning, of the Automotive Section of the War Industries Board, pointed out that the motor truck has the greatest chance for development in the history of the industry. He pointed out the possible use for from 100,000 to 300,000 motor trucks in the parcel post delivery system of this country, and said that it was necessary for motor truck manufacturers to get behind legislation in Washington to make this possible. With the use of motor trucks in this work made possible through government legislation, the various truck companies would advance the idea of the necessity of the motor truck much more rapidly than they would if they should first try to sell their trucks separately to the Post Office Department. It was also his opinion that the motor truck has not yet been sold to the country at large, and that the surface of the possibility of motor truck use has only as yet been scratched.

Plenty of Gasoline

One of the startling statements made by H. L. Horning was to the effect that there is an over-production of gasoline to-day of more than 1,000,000 gal. a day.

Mr. Horning, in his official capacity in Washington, has already been in receipt of many inquiries from motor truck manufacturers as to obtaining priority orders for the shipment of goods entering into motor truck manufacture, and brought out the fact that notwithstanding that these makers have A-1 priority orders, they could still not get materials. In his opinion, the remedy for this difficulty lies in the motor truck establishing its status as a national necessity. If motor truck makers can prove to the Government the necessity for using more and more motor trucks in order to relieve the freight congestion and can actually relieve it, the status of the motor truck will become firmly fixed and there will be no question as to the various makers not getting sufficient material to produce their vehicles.

He further pointed out that the motor truck is the means whereby our armies in the field can strike the blows which will result in defeating the Germans. The trucks carry the ammunition, the food and all sorts of military supplies, without which these sledgehammer blows cannot be given.

The need for a Federal statute controlling the operation of motor trucks in every State of the Union was the outstanding feature of the talk given by Windsor T. White, chairman of the N. A. C. C. Commercial Vehicle Committee on "Legislation Affecting the Use of Motor Trucks." Mr. White's paper treated of the present non-uniformity of existing laws regarding the operation of motor trucks, and the fact that a truck owner operating his vehicle in more than one State would have to equip his trucks with different sized tires if the various laws were carried out to the letter. In

Coal, the Avenue To Curtailment

Coal-Budget Plan Devised To Curb Non-War Industries by Fuel Administration

WASHINGTON, D. C., Jan. 9—The Fuel Administration has worked out a budget plan of coal allowance by percentage for 1918 to all industries not immediately essential to the conduct of the war and the National interests—and the automobile industry is included in this classification. In other words, the Fuel Administration despite its assurances of no unessential classification, is still headed in that direction. The long forecasted curtailment and stigmatizing classification made in these columns in past issues is again threatening. However, the new plan contemplated by the Fuel Administration does not include issuing a list of the so-called non-essential industries. It is not so brutal. The battle-axe method has been discouraged. A more polite, painless and quiet plan is now adopted. In place of the brutal and direct classification of industries as non-essential, the Fuel Administration expects to force each industry to classify itself as not being essential to war.

The Coal Budget Plan

The method is called the "coal budget plan." Committees representing the large industries of the nation not engaged immediately in war work will be called into conference with the officials of the Fuel Administration. They will be told the amount of coal available for all purposes, the quantities required for war purposes and domestic consumers and the total curtailment of the use of coal necessary to satisfy these demands. They will be asked how they are regarded and what standing they have as to their essential qualifications with the war industries board. They will be asked to volunteer a reduction of their coal consumption for 1918. They will be asked to show the Fuel Administration the best way to accomplish this curtailment and as to how to arrange restrictions so as to affect only the less essential portions of their own business if possible. For example, the Fuel Administration intends to call in the Automobile Industry Committee and try to learn how many passenger cars are used for pleasure and what percentage are used for utilitarian purposes and will then attempt to cut the coal supply to the automobile factories from 100 per cent down to a point in proportion to the percentage of passenger cars required for war work. About one dozen industries have already been called into conference and results promise a saving of 20,000,000 tons, while the total offering from all non-war, which is the new word used instead of non-essential, industries is exepected to be 50,000,000 tons.

The Fuel Administration asks that the automobile industry get in touch with it without waiting for formal notice. It believes that this new plan of voluntary conservation will "forever lay the ghost of the 'cut off the non-essential industries' agitation."

Fuel needed in 1918 for army and navy purposes, for munitions works, for public utilities, for domestic consumers and for factories engaged in war work is scheduled in the budget for 100 per cent fulfillment. With this figure and the estimated production of coal in 1918 as a basis a subtraction shows the amount left for non-war industries. The Fuel Administration when queried about the estimated production for 1918 replied that it was impossible to formulate such an estimate.

Backbone of Industry

Dr. Garfield, head of the Fuel Administration, stated that he realizes that the non-war industries, which have sometimes, as he put it, been miscalled non-essential industries, are the backbone of the country's economic system and that they employ 10,000,000 workers upon whom the nation must depend for bonds and taxes to pay for the war. The percentage of reduction, according to the Fuel Administration, will vary partly upon the advice of the leaders of the industry as to what is practicable and safe shrinkage as compared with the business activity of 1917, and will also partly vary with the character of the business, which means that in proportion as an industry contributes less to the war or domestic necessities it will naturally increase its contribution of self-limitation.

The plan has two advantages aside from the disadvantage of curtailment and stigmatizing classification, and these are:

1. Its elasticity, which will be equalized if the coal production for 1918 is found to be more or less than is now anticipated.

2. Its ability to secure equal compliance by every member of each industry, thus assuring equal sacrifice and no unscrupulous advantage by competitors.

—

New Government Labor Plan

WASHINGTON, D. C., Jan. 9—A new plan of labor policies and program for securing labor has been worked out by the Secretary of Labor and the Council of National Defense. The plan includes:

1. A means of furnishing adequate and stable labor supply to war industries by use of a system of labor exchanges, methods of training workers, establishment of an agency for determination of priorities of labor demand, and agencies for dilution of skilled labor.

2. Machinery to provide for immediate and equitable adjustment of disputes between labor and capital without stoppage of work and dealing with wages, hours, shop conditions, etc.

3. Machinery for safeguarding conditions of labor in production of war essentials, including industrial hygiene, safety, women and child labor, etc.

4. Machinery for safeguarding conditions of living, including housing, transportation, etc.

5. Organization to assemble necessary labor data.

6. Information division to develop public sentiment, promote local machinery in industrial plants to help carry out the national program.

Of these agencies the mediation service, labor exchange and bureau of statistics are already in existence. The Secretary of Labor expects to call in for assistance a well-balanced corps of experts representing capital, labor and the public.

Expect $5,000,000 Shell Contract

Jackson Manufacturers Organize $500,000 Corporation to Handle Government Work

JACKSON, Jan. 5—The Jackson Munitions Corp., formed by local manufacturers and business men, and incorporated for $500,000 for the purpose of manufacturing shells, has practically secured a $5,000,000 Government contract. Mayor William Sparks of the Sparks-Withington Co., prime mover of the organization, will spend next week in Washington completing the arrangements, and after his return the board of directors will be elected. Arrangements have been practically completed whereby the plant of the Mutual Motors Co. will be used for the manufacture of large shells, and that of the Jackson Automobile Co. for smaller shells. The smaller industries in the city will also receive proportionate parts of this and other contracts. It is stated that the Government desires the $5,000,000 contract completed by next September. At present about thirteen of the Jackson factories are engaged in Government work.

—

Record Sales in Vancouver

VANCOUVER, Jan. 5—The past season has been the most successful in the memory of dealers. Since the beginning of June last, no less than fourteen hundred cars have been sold in local territory. Reports from the local licensing department tend to show also that winter is having little or no detrimental effect on sales. Medium-priced cars have held the lead in point of sales. That the Province of British Columbia is a prolific field, still virgin soil so far as the automobile industry is concerned, is evidenced by the fact that new companies are stretching their tentacles to include the farthest west Province of the Dominion.

One matter that is causing no little concern to dealers locally is the question of deliveries. So far, Vancouver dealers have been singularly fortunate in keeping pace in large measure with demands but it is almost too much to expect that this gratifying state of affairs will continue during 1918.

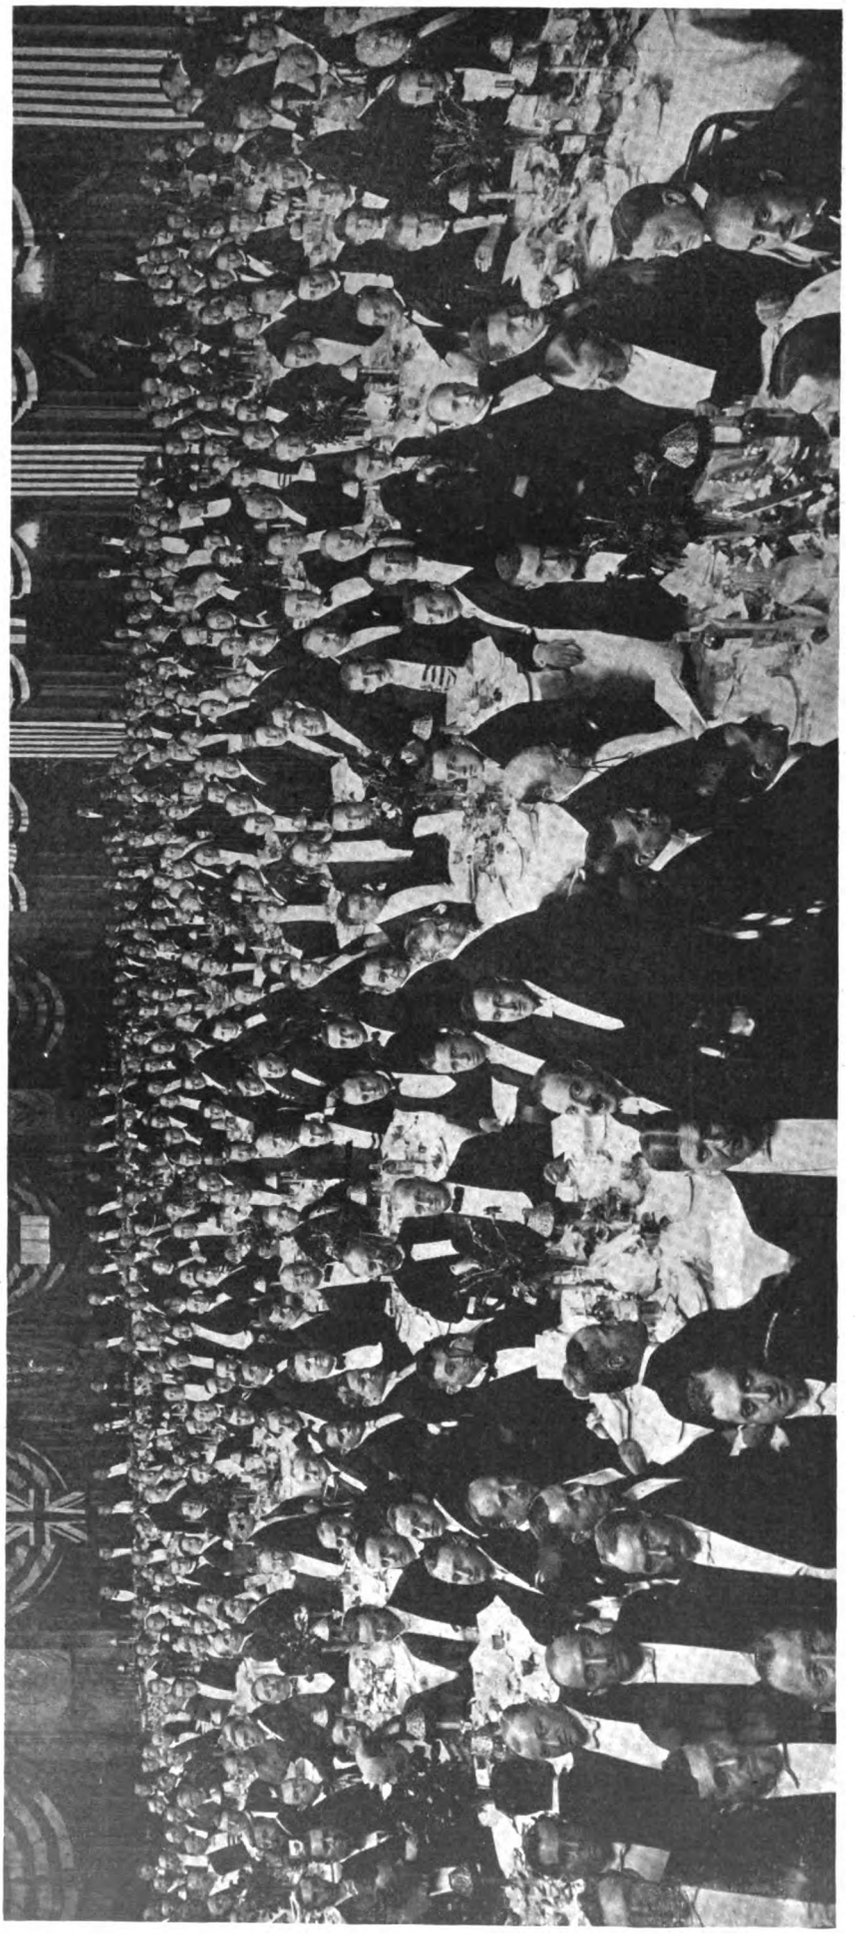
Vanderlip Preaches Economy

Financier Tells Rubber Club Greater Efficiency, Too, Is a Prime Requisite Today

NEW YORK, Jan. 7—Frank A. Vanderlip, of the National City Bank, and who is now operating for the Government in connection with the war thrift stamp loan campaign, addressed the Rubber Assn. of America to-night at the Waldorf-Astoria, and reiterated those policies which he has been mentioned before as expounding.



Mr. Vanderlip maintained that the individual in our nation should be more economical, and that he should not spend money. He maintains that if we are to win the war we must cease to buy many of the things we have purchased in other years; that we must cease to buy what he termed luxuries, and he is credited with having indicated earlier in the day that the motor car was non-essential. The car, by the way, has long since ceased to be classed by our Government as a non-essential.

Mr. Vanderlip talked of the need for greater factory capacity, but he did not point out any particular use that would be made of factory capacities if all the factories in America offered themselves to the Government to-morrow. He talked of the need for releasing labor for Government work, but he did not point out where men are needed, what they are needed for or anything of that kind.

He is also credited with having stated previously that if a man's old hat will last 6 months longer he should not buy a new hat until 6 months from to-day. He said some people fear that we may disorganize business. He said: "The tragedy of it is going to be that we are not going to disorganize certain kinds of business enough. In the period of such tremendous prosperity, in a time when the wage fund is so great, when the profits of agriculture are so tremendous, it is going to be impossible to take this lesson of economy with 100 per cent efficiency to 100,000,000 people. What I fear is that we shall have the greatest business in luxuries we have ever known, that people will unconsciously exercise their command over labor, over material, over shop room and transportation, and will interfere with outfitting this army."

He said the Government had appropriated $19,000,000,000 for the purchase of raw materials and had been unable to spend this money because there were not enough things produced to spend it for. He did not agree with the policy that we must expand our industries to promote greater production, but indicated that we must cease some of our production in order to make room for war work, which is contrary to the idea of the expansion of industry that is now recognized by most of our readers as the only sound course to follow.

He also stated that the breakdown of

The annual banquet of The Rubber Association of America, held at the Waldorf in New York, Jan. 7

Digitized by Google

the railroads began long ago, and that it was due to the form of Government control that had been exercised. He said we doubtless have seen the end of Government control as we have known it in the past, and he was loudly applauded by the rubber men when he indicated that greater leniency should have been shown to the railroads, and that they should have been permitted to advance rates and put profits on a better basis during the period when costs of all kinds were rising rapidly.

—

Rubber Association Elects Works President

NEW YORK, Jan. 8—The Rubber Association of America has elected new officers. They are: President, B. G. Works, president of the B. F. Goodrich Co.; first vice-president, H. Stuart Hotchkiss, formerly with the United States Rubber Co. and now in government work; secretary-treasurer, H. S. Vorhis, re-elected.

—

First Aviators Graduate

WASHINGTON, D. C., Jan. 8—The first group of completely trained American aviators ready for service has been graduated by the air school nearest the front line in France. The men have completed the final courses in aerial photography and observation. All received their commissions with one exception.

Champion Ignition Develops A. C.-Baldwin Speedometer

Will Produce Magnetic Type Named for Albert Champion and Russell Baldwin

NEW YORK CITY, Jan. 10—A new speedometer has been developed, known as the A.C.-Baldwin, which is to be made by the Champion Ignition Co., Flint, Mich. It is a magnetic type, which has been under development for over 2 years and has been tested out very extensively. It will be manufactured at the Champion spark plug factory, the plans being to erect new buildings for its manufacture. Production will not start for some months. The speedometer takes its name from the initials of Albert Champion, coupled with the name of Russell Baldwin who developed the instrument. Mr. Baldwin was for years connected with the Stewart Speedometer Corp.

—

"Hot Spot Demonstration"

NEW YORK CITY, Jan. 8—A demonstration showing the value of the Chalmers "Hot Spot" manifold was made today by having one of the touring cars stand for 15 hours on the street near the Grand Central Palace under the observation of an official observer. The motor was stopped for that period during which thermometers showed the temperature to average below 30 deg. Fahr. all the time. At 10:30 at night, after the 15-hour stop, the motor was officially started. It required 8 seconds with a starter before the first explosion occurred. After this there were one or two stops when the starter had to be again used but 41 seconds after the first attempt the motor took hold and began accelerating.

—

Reo Prices Changed

DETROIT, Jan. 9—The following prices on Reo models will be effective immediately:

Model	Price
R, 4-cylinder, with rod top— roadster	$1,285
S, 4-cylinder	1,085
(same with Rex top)	1,260
T, 4-cylinder (either touring or roadster model)	1,225
M, 6-cylinder touring or roadster	1,550
(either rod or Bonnet top).	200 extra
F, Speed wagon chassis	1,100
(with express body)	1,175
J, 2-ton truck	1,800
(with stake body)	1,950

—

Schwerdtseger Air-O-Flex Engineer

DETROIT, Jan. 10—F. W. Schwerdtseger has been appointed designing engineer of the Air-O-Flex Automobile Corp. He was formerly chief engineer of the United States Motor Truck Corp. and latterly has been connected with the Federal and Denby companies.

Motor Trucks Will Help Win the War

(*Continued from page* 145)

some cases the trucks which could be operated in one State could not be run in another on account of the difference in the existing laws.

S. M. Williams, of the Garford Co., Lima, Ohio, made an appeal for the immediate building of national highways suitable for continuous motor truck traffic. These roads will have to come first because our present thoroughfares are not able to withstand the greatly increased amount of freight which trucks will have to carry over them within the next year.

J. F. Winchester, secretary of the Motor Truck Club of New Jersey, told of unfair laws controlling the operation of motor trucks in his State, and of how from 60 to 70 per cent of all the trucks operating in New Jersey at the present time will be barred if the new law were inforced to the letter. He brought out the fact that according to the present law, which went into effect Jan. 1, 1918, 5-ton trucks like the Pierce-Arrow, Packard, Mack and others which carry over 66 per cent of their total load on the rear wheels, would not be allowed on the road if the present reading of the law that not more than one-third of the total weight be carried on any one wheel were strictly enforced.

Roy D. Chapin, chairman of the Highways Transport Committee, told of the great need of transportation in order to win the war. He mentioned the inadequacy of our present rail, inland water and ocean transportation, and of the great possibility of motor truck haulage provided suitable roads were built and properly maintained.

The great reliance which the Government departments are now placing upon the motor trucks was brought out by a request made to the Highways Transport Committee by the Shipping Board asking that the war trucks driven overland carry parts of ships now urgently required at the yards along the Eastern seaboard. The work which trucks can accomplish in relieving the present terminal congestion was also discussed, and the necessity for good roads kept opened all the year around made evident the trucks were to succeed in this important work.

The problem of return loads must also be solved if the trucks are to operate at their maximum efficiency. Mr. Chapin told of the plan now being introduced in the State of Connecticut in which a Return Loads telephone number be placed in the telephone directory of each city. Then if a driver carries a load from one city to the other, all he has to do is to call up Return Loads in the city to which he has driven and inquire if there are any loads to be returned to the city from which he has come.

George H. Pride, also a member of the Highways Transport Committee and himself an operator of a large fleet of motor trucks, told of the great possibility of motor truck use in emergencies where time is paramount; in the delivery of express material; in the haulage of high grade or high rate L. C. L. freight shipment; of the possibility of eliminating grating when goods are hauled by trucks, and of combined long inland water way hauls by garages and short motor truck hauls at each end of the route.

The positive need for a new type of motor truck road built upon a new engineering and logical basis was gist of the remarks of George C. Diehl, who is chairman of the Good Roads Committee of the American Automobile Association.

The necessity for and the probable appointment of one centralized Government purchaser of motor trucks in Washington was the high spot of the important address of Christian Girl, director of production, military truck division, Quartermaster Department U. S. A. Mr. Girl outlined briefly the development of the Government motor truck program and of the necessity of the truck industry selecting a representative in Washington to assist the Government in carrying out this vast undertaking. He favors putting the burden of the production of suitable motor trucks in sufficient quantities to make possible the Government's ambitious program directly upon the motor truck industry. Such a move would greatly simplify matters and will undoubtedly come to pass within a short time.

Formula for Tractor Radiators

Slower Fan Speeds and Larger Sizes Recommended — 3% Engine Power for Fans

MINNEAPOLIS, Jan. 5—With the thought of clarifying the atmosphere with regard to radiators for farm tractors, and the many problems connected therewith, A. B. Modine, of the Modine Mfg. Co., manufacturer of tractor radiators, gave one of the most comprehensive expositions of this subject that has ever been given, before the Minneapolis Section of the Society of Automotive Engineers at its January meeting.

Mr. Modine really spilled the beans so far as the tractor radiator question is concerned and spoke in no uncertain terms as to what were the necessities in the way of changes for tractor cooling. After discussing the questions of temperature rise in the air to that of the velocity of the air, he proposed a standardized air velocity to gross radiator area of 2000 ft. per minute.

Mr. Modine went into the question of fan capacity, and stated that while as high as 4½ per cent of the engine power was in some cases necessary to drive the fan, he believed not more than 3 per cent should be required. He recommended larger fans and slower speeds as a means of higher efficiency, and submitted a series of sizes and speeds for fans suitable for different engines ranging from 20 to 50 hp.

Mr. Modine has made a very broad investigation of temperature rise of the air, with the result that during the year there should be a conservation of several million pounds of copper in radiator construction, which copper otherwise would have been needlessly used. In this work he approached the subject under two heads, namely, water delivery and air velocity.

The amount of heat given off from a source is proportional to the difference in temperature between the radiating body and the air. Further, the loss of heat by convection is nearly proportional to the difference in temperature between the hot body and the air. With this accepted, the problem is that of maintaining the surface of a radiator at as high an average temperature as is practical, and this becomes a question of water circulation.

The subject then becomes a question of choosing a standard for circulation that will give practical pump sizes and still maintain a reasonably small temperature drop throughout the radiator.

With this problem in view, Mr. Modine proposed as a standard a rate of water circulation that will give a temperature drop to the water circulated through the radiator of not more than 5 degrees.

In applying his conclusions Mr. Modine declared that such a standard would check up well with that group of tractor engines of 20 hp. providing a few of the engines would run their 18-in. fans at a higher speed than 1450 r.p.m. In the 30-hp. division L-head engines the radiators used show an actual size of 12 per cent larger than that proposed by the Modine standard.

In the 30-hp. valve-in-the-head division the radiator based on the Modine standard would be 3 per cent larger than that in actual use. The same is true of the 35-hp. L-head engine division. In the 40-hp. division the radiator size required under the Modine formula checks exactly with the size of radiators in use. In the 50 hp. size the formula radiator is 12 per cent larger than those in use.

After a further analysis of radiator size in relation to engines, Mr. Modine recommended larger fans with slower speeds, and declared that the power consumption for fan drive should not be more than 3 per cent of the rated engine power. He considered that a consumption of 4½ per cent of the rated engine power for fan drive is too high.

—

Triangle Truck Prepares for Production

ST. JOHNS, MICH., Jan. 8—The Triangle Truck Co. has increased its capital stock from $50,000 to $100,000 and is preparing for active production. The first 1½-ton truck was completed this week and a new factory is in process of construction.

—

National Hearse to Issue $100,000 Stock

GRAND RAPIDS, Jan. 8—The National Hearse & Motor Co. will issue $100,000 of 7 per cent preferred stock, with dividends payable quarterly, in order to take care of the increasing business. The company is operating at full capacity, and sells $40,000 worth of cars each month. The business for 1918 shows an increase of 100 per cent over that of last year.

—

General Vehicle Plant Sold for $861,000

LONG ISLAND CITY, Jan. 8—The plant of the General Vehicle Co. has been sold to the United States Government. The consideration was $861,000, and not $2,500,000, as was rumored last month.

1000 S.A.E. Members Added in 1917

Membership Increased 47% and Now Totals 3119—Big Dinner Attendance Sure

NEW YORK CITY, Jan. 9—At the closing meeting of the 1917 Council of the Society of Automotive Engineers held to-day, the rolls of the society showed a total membership of 3119 as of Jan. 1, 1918. This represented an increase of 998 members during the year. As the membership a year ago was 2121, the increase during the year approximated 47 per cent.

The membership committee reported that for the S. A. E. War Dinner to be held in Chicago, Friday, Feb. 1, approximately 861 tickets have already been sold. This gives evidence that the entire seating capacity of the New Morrison Hotel should be sold out some time in advance of the meeting.

For the Special Motor Boat Dinner to be held in New York, Friday evening, Jan. 25, nearly 100 tickets have already been sold.

The total seating capacity of 1000 at the Automotive Industries Dinner at the Hotel Biltmore on Thursday evening, Jan. 10, in connection with the annual meeting of the society, has been taken up, and there is a waiting list of over fifty.

It is possible that there will be a special tractor dinner at Kansas City in connection with the tractor show to be held in that city.

—

Kanary Manager for United Motors

GRAND RAPIDS, Jan. 8—M. H. Kanary has been appointed general manager of the United Motors Co., succeeding George P. Sweet, who recently resigned to accept a commission as lieutenant in the motor truck division, Aviation Section of the Signal Corps, at Washington, as was previously announced in AUTOMOTIVE INDUSTRIES. Kanary is president and general manager of the Samson Trailer Corp., Grand Rapids, and also president of the Chicago Structural Steel Co., Chicago.

—

Fuller & Sons in New Plant

KALAMAZOO, MICH., Jan. 8—The Fuller & Sons Mfg. Co. is now manufacturing in its new plant. This plant has approximately 100,000 sq. ft. of floor space, and consists mainly of reinforced concrete buildings of fireproof construction. Steel sashes are used to give a maximum amount of daylight, and the building is heated by forced circulation.

—

Fire in Perlman Rim Factory

JACKSON, MICH., Jan. 9—The Perlman Rim Co. was damaged to the amount of $100,000 yesterday by a fire supposed to be of incendiary origin. The Government work being done in the factory was not affected, and the general production will be delayed only 48 hours.

—

King Prices Increased

DETROIT, Jan. 7—The following are the prices on the new models manufactured by the King Motor Car Co.:

Model	Former Price	Present Price	Increase
7-pass. touring	$1650	$2150	$500
4-pass. Foursome	1700	2350	650
3-pass. roadster	1585	2150	565
7-pass. convertible sedan	2300	2950	650

Wire wheels are extra on all models except the Foursome, and this is regularly equipped with wire wheels and 32 x 4½ cord tires.

—

New Prices for Dort

NEW YORK, Jan. 5—New prices for the Dort were made public to-day. The five-passenger touring car and the roadster, which were $725, are now $865. In the four-season line, the sedan, which was $1,095, has been made $1,265; the sedanet, a convertible type, has been raised from $845 to $1,000. A new coupe model not heretofore manufactured has been brought out at $1,265.

10 Per Cent Drop in Exports

November Shipment $1,114,767 Less Than October—Average for 11 Months Correct

Mos.	1917 Cars	Value	Trucks	Value	Parts
Nov.	5006	$4,820,738	1435	$3,430,162	$2,535,230
Oct.	5536	4,481,127	1333	4,374,470	3,045,300
	1916				
Nov.	5337	4,016,930	1655	5,175,114	2,151,434

WASHINGTON, Jan. 8—Export figures for the month of November show a decrease in value for that month as compared with October, of 10 per cent. There were 530 less passenger cars exported, but the increase in value shows a gain of 7 per cent, equal to $339,611. Although the number of trucks exported during November was 102 greater than the October figure, there was a decrease in value of $944,308, or 27 per cent. The decrease in the value of parts exported was 17 per cent.

Australia was our largest customer for passenger cars, having purchased 673 at a cost of $551,859. Argentina followed with a bill of $355,443 for 485 cars. England bought almost the entire shipment of trucks, since 1037 out of a total of 1435 exported were sent to the United Kingdom. The value of the trucks shipped there was $2,472,390.

The most noticeable drop was the number of cars sent to Canada. During October, 1020 at a cost of $676,483 were sent, but the November figure is only 325 cars at a cost of $291,838. Likewise, Canada's truck purchases in October amounted to $69,709, whereas in November they were only $36,092.

The shipment for the month of November likewise shows a decrease of 5 per cent or $557,348 as compared with November, 1916. The figures for November, 1917, in spite of the decrease maintain a correct average for the year, being almost exactly 1/11 of the value of exports for the 11 months ending Nov. 30, 1917.

Exports of Automobiles, Trucks and Parts for November and Ten Previous Months

	November				Ten Previous Months

Second Truck Train Ends Trip

46 Pierce-Arrows Arrive at Governor's Island After Trip from Buffalo

NEW YORK, Jan. 8—The largest fleet of government war trucks yet driven overland arrived at Governor's Island today after a 300-mile trip from the factory of the Pierce-Arrow Motor Car Co., Buffalo, N. Y. The train consisted of forty-six 5-ton Pierce-Arrow trucks, manned by 100 members of the Twentieth U. S. Engineers in command of Capt. J. K. De Loach and Lieut. G. C. Eastman. The convoy left the Pierce-Arrow factory on New Year's morning and ran east across the State to Albany and then followed the Hudson River Valley on the eastern side of the river down through Ossining, Peekskill and Yonkers to New York.

Much Snow Encountered

Much snow was encountered on the trip and the temperatures often fell below zero, requiring that the trucks be given the best of care in order to prevent the engines from freezing up. Very little preparations had been made by the State Highway authorities, so that the leading truck of the fleet was equipped with a snow plow to clear away the drifts so that the rest of the train could follow. The personnel of the fleet was treated royally in every one of the large cities through which the train passed.

The trucks were made up into three sections, each accompanied by a trained Pierce-Arrow mechanic to assist the drivers in making repairs in case of trouble on the road. Two drivers were assigned to each truck and motorcycle outriders kept Captain De Loach in touch with the three sections all along the route.

Drivers Billeted in Factory

The men of the Engineering Corps which drove the trucks received a week's training at the Pierce-Arrow plant before the start of the trip. They were billeted in the Pierce-Arrow plant, where a large room was cleared for the purpose and where the men set up their folding cots that form a part of their regular equipment. Meals were served in the main dining room of the factory and smoking and lounging rooms were set aside in another part of the factory for the drivers' comforts.

Operators Were Trained

Each of the men underwent an intensified week of instruction laid out by the Pierce-Arrow truck engineers in order to familiarize him with the details of construction and the operation of the truck. The standard instruction book furnished by the Pierce-Arrow company was used but augmented by special lectures on the various parts of the equipment. The last portion of the course was devoted to intensified road driving under the watchful eye of expert instructors of the Pierce-Arrow company.

Before the beginning of the trip, all of the men received some actual overland driving experience when twenty-three of the trucks, lacking bodies, were driven to Dunkirk, N. Y., 47 miles from Buffalo. At Dunkirk each truck was fitted with a body, an extra body loaded in knocked-down form, and the entire fleet driven back to Buffalo.

—

Gotfredson Heads Saxon

DETROIT, Jan. 10—Benjamin Gotfredson was elected president of the Saxon Motor Corp. at a meeting of the board of directors held in New York this week. Mr. Gotfredson will take the place formerly occupied by Harry W. Ford. He has been a stockholder in the Saxon organization for some time and has been more or less identified with the activities of the company. Mr. Gotfredson is president and organizer of the American Auto Trimming Co., Detroit.

—

Abbott Sees Trouble

OVERLAND, OHIO, Jan. 4—An involuntary petition in bankruptcy was filed in the Federal Court Friday against the Abbott Corp., manufacturers of the Abbott passenger car. It is estimated that the assets of the corporation are $50,000 and the liabilities about $200,000. A. W. Gardiner, secretary of the Abbott Corp., states that the assets will reach a much higher figure. Concerning the bankruptcy proceedings, the statement of the company is that the plant has temporarily suspended operations, and that it is still believed that the contemplated merger of the Abbott Corp. and the Hal Motor Co. will still go through. It is the plan of the combine to make Abbott and Hal passenger cars, and bring out a motor truck.

—

Government Wants Women Drivers

WASHINGTON, D. C., Jan. 8—The Depot Quartermaster of the War Department has asked the Civil Service Commission to provide a list of women eligible to drive motor trucks. The Department will use one hundred women motor truck drivers on the streets of Washington at $70 per month to start. None of the drivers will be sent abroad.

—

Labor Department Has New Bureau

WASHINGTON, D. C., Jan. 8—The Department of Labor has organized a new bureau called the United States Employment service, which is an enlargement of the previous immigration service and includes the two auxiliary bodies, the United States Public Service Reserve and the United States Boys' Working Reserve. It is planned to secure the mechanics needed in the shipbuilding industry through this new bureau. J. B. Densmore has been appointed National Director and will be assisted by Robt. Watson and Charles Clayton.

Vanderlip's Opinions Criticised

Industrial Organizations Object to His Proposed "Labor Saving" Methods

NEW YORK CITY, Jan. 9—The views of Frank A. Vanderlip, president of the National City Bank, and who is now making speeches on the war-saving certificate problem, are arousing the criticism of many industrial organizations, which take objection to his statements that those industries not directly connected with the war should go out of business in order to liberate labor or what Mr. Vanderlip describes as more necessary industries. Automotive Industries for 2 weeks has been taking issue with Mr. Vanderlip's statements, showing that there is not the shortage of labor which he would have it understood there exists, and that shortage of clothing for the soldiers was not in any wise due to workers being used in industries which Mr. Vanderlip would put out of business.

It is believed that the National Automobile Chamber of Commerce has been taking cognizance of Mr. Vanderlip's statements and that not a few organizations, among which might be mentioned certain communities of department stores, will take issue on the points in question.

It would seem an opportune time for various industrial organizations that are the subject of Mr. Vanderlip's remarks to bring together the desired information on this subject. They would be performing a patriotic service in a presentation of the situation that would state the facts.

—

Kendall Tire Option on Ben-Hur Plant

WILLOUGHBY, OHIO, Jan. 3—The Kendall Tire & Rubber Co., Akron, has taken an option on the 9-acre plant of the Ben-Hur Motor Co. here. The factory is a 2-story, 150 by 400 building.

—

Goethals Also Transportation Head

WASHINGTON, D. C., Jan. 8—Major-General George W. Goethals of the Quartermaster Corps has been appointed to serve also as Director of War Department Transportation. This means a co-ordination and co-operation of motor truck design and production and insures economy in the use of them and in their maintenance. In the past the Ordnance, Engineers, Signal Corps, Aviation Service and Coast Artillery have been purchasing trucks, tractors and other motor vehicles individually.

—

New Engine Company in Brooklyn

BROOKLYN, N. Y., Jan. 8—The High Efficiency Motor Corp. has been organized with $200,000 capital by R. E. Weber and W. Rabsilber, Brooklyn, and M. Lewenthal, Hoboken, N. J. The company will manufacture motors, engines and automobiles.

Industrial Review of the Week

A Summary of Major Developments in Other Fields

ANTHRACITE PRODUCTION FAVORABLE

The production of anthracite was naturally slightly curtailed last week on account of the holidays. This curtailment, however, was not as great as is often the case, since many of the miners observed only Christmas Day and did not take the three days to two weeks' lay-off which they frequently do at this season of the year. The intense cold which descended upon the eastern portion of the United States with temperatures in many instances well below the zero mark, and exceptional for this territory, coupled with a decided shortage of fuel throughout the East generally, caused considerable suffering in many localities. So far as is known, little advantage was taken of the stringent conditions by small retailers to boost the price to exorbitant levels. One or two instances of this kind have, however, come to light, and the offenders were promptly arrested. The larger towns and cities, while suffering to a considerable degree, were probably not in as bad condition as some of the country districts. Centers of dense population, such as New York and Philadelphia, may be relieved of coal scarcity much more easily than where the population is scattered. The orders of Secretary McAdoo throwing open to coal traffic the passenger tunnels of the Pennsylvania Railroad doubtless do much to relieve fuel scarcity in some of the boroughs of New York City.

The demand for bituminous coal shows no signs of lessening or abating. The steam demand, which has for months been insistent, is now quite as much so as ever. Many industrial plants, some of them engaged in war munition work, have been compelled to shut down for more or less extended periods, while many others are operating on a day-to-day supply. As has been the case heretofore, much of this stringency could be relieved if transportation facilities were available. There is little question but that New England, which ordinarily gets a large portion of its soft coal by water, will this year be compelled to ship it in all-rail from the mines of Pennsylvania and West Virginia. There is not, and of necessity will not be, much choice exercised as to the grade or quality of coal to be secured. What is needed is something that will burn and make steam. It makes little difference whether this is slack, run-of-mine or lump. The price is, and has been for some time, an entirely secondary consideration. Transportation facilities have also been considerably affected by the cold weather throughout the Middle West. In this region many mines are working two or three days per week where the operators and miners would gladly work them six or possibly even seven days per week if cars for loading could be secured. It is yet too early to say what government control of the common carriers will do to relieve the situation, but it is strongly hoped that a gradual improvement will take place. Many schemes have been brought forward, tending toward the conservation of fuel. Among the most prominent means is that of lightless nights. In many cities one or two such nights are observed each week, while it is strongly urged that at least six be observed in the future. Lightless nights at present means the abolition of glaring electric signs and similar electrical displays. In many instances the abolition of street lighting, either wholly or in part, might well be followed. It would appear that at least when the moon is full, or nearly so, and the ground is covered with snow, there is little real need for street lighting except at dangerous street crossings and similar localities. Throughout the entire country there is a decided and insistent demand for both domestic and industrial fuel.—*Coal Age.*

A New Service

¶ Herewith AUTOMOTIVE INDUSTRIES *supplies for the benefit of its readers a general summary of important developments in other fields of business. This is rendered possible by the editorial co-operation of leading industrial publications which are recognized authorities.*

By compressing the general industrial situation into this form we hope to give our readers a clear and comprehensive idea of up-to-the-minute developments which they could otherwise secure only with considerable expenditure of time and effort.

BLAST-FURNACE OPERATION DEMORALIZED

The first week in the new year has brought blast furnace and steel works' operation to the verge of complete demoralization. Western blizzards have made vastly worse what has been for weeks a serious situation and embargoes on shipments have made conditions at rolling mills almost hopeless.

Scores of blast furnaces have been banked in the Pittsburgh, Youngstown, Wheeling, Cleveland and Chicago districts. Steel works in the same territories have been able to operate at but 50 to 75 per cent of capacity. The East, while spared fresh snow blockades, has had record low temperatures and so little fuel has been delivered to steel plants that working schedules have gone to pieces. Never has the industry been so generally crippled or with so poor a prospect of any early return to normal conditions.

December pig iron statistics show the sharp cutting down of production in the second half of the month, and the January showing will doubtless be worse. The total of coke and anthracite iron last month was 2,882,919 tons, or 92,997 tons a day, against 3,205,794 tons in November, or 106,859 tons a day. Capacity active Jan. 1 was only 93,500 tons a day, against 106,953 tons on Dec. 1 and only 324 furnaces were in blast Jan. 1, a loss of 24 in the month.

So far as the market is concerned, the relation of supply and demand growing out of the serious operating conditions is secondary to question of Government price fixing. Reasoning that price changes will almost certainly be downward, buyers find no reason for contracting except that of getting a none too certain place on rolling mill schedules, and sellers are not making haste to write contracts that are likely to be revised from without.

Among questions raised by buyers is this: If there are new prices April 1 will they apply to deliveries carried beyond that date, even though contracted to be made in the first quarter? An authoritative answer is that they will.

Lower Prices Coming

While Washington assurance is given that no price changes are contemplated that will reduce steel production by going below costs of small producers, there is an evident purpose to reduce prices obtained by integrated companies. By the Pomerene bill or in some other way a Government control is aimed at that will take over all output, but at different prices to different producers. The market price would then be an average and not at a level fixed by the costs of high cost plants. In the face of such a proposal the steel trade has modified its first feeling of satisfaction with the recent official action on present prices.

Lake Superior ore producers, who make sales for an entire year, are organizing a protest against a possible revision of their 1918 contracts. Thus far considerable reservations of ore have been made at Cleveland, but actual sales are deferred until prices can be definitely fixed.

Hundreds of thousands of tons of export steel is piled up at Eastern ports awaiting shipment, and large sales for export could be put through if bottoms could be had. In wire a 50,000-ton inquiry has been up, but could not be entertained. The Government is seeking 50,000 tons of open-hearth rerolling billets for shipment abroad.—*Iron Age.*

Men of the Industry

Changes in Personnel and Position

Disbrow Joins Moore Motor Vehicle

MINNEAPOLIS, Jan. 7—Louis Disbrow, famous automobile racer and engine designer, has joined the Moore Motor Vehicle Co. in the capacity of chief engineer. After attending the New York and Chicago shows he will assume full charge of the engineering department of the Danville factory.

—

E. B. Foote has resigned from the sales managership of the New England District of the Mitchell Motors Co., Boston.

—

Walter Bamford, formerly with the Detroiter Motor Car Co., Detroit, has become production manager of the Fulton Motor Truck Co., Farmingdale, L. I.

—

P. W. Litchfield, vice-president and factory manager of the Goodyear Tire & Rubber Co., Akron, has been appointed a member of the War Service Committee by the Rubber Association of America. He will represent the rubber industry in its co-operative relations with the Government.

—

Thomas Wetzel has been elected vice-president of the Buffalo Pressed Steel Co., Inc., Buffalo, N. Y.

—

C. J. Cunningham has been promoted to the position of general service manager of the Detroit Weatherproof Body Co., Pontiac, Mich.

—

Arthur H. Wyatt has been elected president of the Pan-American Motors Co., Decatur, Ill. He has been with the company several years.

—

John B. Orman, who has managed several automobile shows in Indianapolis, was chosen by the Indianapolis Automobile Trade Association to conduct the 1918 show, which will be started Feb. 25.

—

J. R. Coleman, who has been chief engineer and assistant general manager of the Atterbury Motor Car Co., Buffalo, is now factory manager in charge of production and purchasing, with the Selden Motor Vehicle Co., Rochester, N. Y.

—

John F. Guider, formerly factory superintendent of the Pierce Arrow Motor Car Co., Buffalo, and an executive of that company for more than 12 years, has been elected vice-president of the Cadillac Motor Car Co., Detroit, and will have charge of manufacturing.

—

Elbert S. Maloney has been appointed manager of the Richmond branch of the Fisk Rubber Co. He was formerly Arkansas representative of the Diamond Rubber Co. and Washington representative of the Goodyear Co.

—

W. E. Palmer has been elected treasurer of the Goodyear Tire & Rubber Co., Akron. He is also secretary of the board of directors.

—

Glenn P. Thayre, manager of the Demountable Wheel Co., Pontiac, has resigned to enter Government service. Walter Brohe is now manager.

—

Benjamin F. Baker has been appointed wholesale representative in New York for the International Harvester Co. He will make his headquarters at the Philadelphia factory branch. Baker was formerly Brooklyn manager and efficiency expert for the Garford Motor Truck Co.

—

Earl W. McGookin has been appointed to represent the Tillotson Mfg. Co., Toledo, in Michigan and Cleveland.

—

C. H. Bassett has been made southern zone manager for the Elgin Motor Car Corp., Chicago.

—

S. H. Woods, formerly with the General Vehicle Co., Long Island City, and the International Motor Co., New York, is now a captain in the Quartermaster's Corps, and is connected with the Military Truck Production Section in Washington.

—

William Field has been appointed assistant sales manager of the Fisk Rubber Co., Chicopee Falls, Mass.

—

Ford Takes Part of Holley Plant

DETROIT, Jan. 7—The Ford Motor Co. is taking over the part of Holley Brothers Co. plant used in the manufacture of carbureters for the Model T car. At present the carbureter company is reorganizing as the Holley Kerosene Carbureter Co., and will manufacture a new kerosene carbureter together with the regular models.

—

Dividends Declared

CLEVELAND, Jan. 4—The Kelly-Springfield Tire Co. has declared the regular quarterly dividend of $1 a share on common stock, payable Feb. 1, to stock of record Jan. 15.

—

WEST CHESHIRE, CONN., Jan. 5—The Connecticut Brass & Mfg. Co. has declared an initial quarterly dividend of $2 a share on its second preferred stock, payable Jan. 21 to stock of record Dec. 31.

—

NEW BRUNSWICK, N. J., Jan. 5—The United States Rubber Co. has declared a quarterly dividend of 2 per cent on first preferred stock, payable Jan. 31 to stock of record Jan. 15.

New Companies Formed

Latest additions to ranks of Automotive Industries

$1,000,000 Company to Operate Carriers

WILMINGTON, DEL., Jan. 3—The Capp Motor Transfer Co. has been incorporated to operate private carriers by water and air. The incorporators are: Seth Bunker Capp, F. R. Hansell, Philadelphia, and J. Vernon Pimm, Camden, N. J. The capital is $1,000,000.

—

To Make Vehicles of All Kinds

DOVER, DEL., Jan. 3—A company to manufacture motor cars and vehicles of all kinds has been organized here under the style United Owners' Supply Co. The incorporators, J. Berliner, P. Zak and B. F. Cowan, Chicago, have listed the capital at $200,000.

—

Russel Co. to Make Tires

NEWARK, N. J., Jan. 3—The Russel Tire Co. has been incorporated with a capital of $100,000 by R. T. Blinder, Frank Hahl and Benjamin Singer. The company will manufacture tires.

—

BUFFALO, Jan. 7—William H. Race & Sons Motor Co. has been incorporated to manufacture engines. The incorporators are William L. Race, L. W. Race and Wilfred E. Race and the stated capitalization is $25,000.

—

Hassler, Ltd., Opens in Canada

HAMILTON, ONT., Jan. 5—Robert H. Hassler, Ltd., has been incorporated and has leased a factory on Sherman Avenue, North. The new company will manufacture shock absorbers for Fords. J. C. Piper has been appointed managing director.

—

Airplane Parts Company Formed

MILWAUKEE, Jan. 7—The United States Aero Propeller Co. has been incorporated with a capital stock of $30,000 to manufacture propellers and other parts for airplanes.

—

Dealers Discard Night and Sunday Service

GRAND RAPIDS, Jan. 4—Eighteen leading dealers here have done away with night and Sunday service, as a means of reducing overhead expenses. In order that service may still be rendered at night, they have designated Bronson's Garage in the downtown section, as an emergency service station for all dealers, and have notified 5000 car owners here of the new plan. Short-time repair jobs will be done night and Sunday by Bronson's Garage, but work which cannot be finished in a short time is turned over to the proper dealer at the beginning of the next day.

Mercury Cars, Inc., to Start Production

NEW YORK, Jan. 7—Mercury Cars, Inc., which was recently formed in New York, is preparing to place on the market a 4-cylinder car powered with a 3½ by 5½ Weidely engine, to sell for $2,750 to $2,950 in open models and $3,600 to $3,900 in closed models. The company has established a factory of limited size at Hollis, L. I., and plans to enlarge this long before active production of cars is commenced, which probably will be mid-summer of this year. The car, the first of which is on view at the Astor salon, is very simple in construction, and has been designed to require the minimum of care. It will have a wheelbase of 114 in.

—

Kelly-Springfield Opens Milwaukee Branch

MILWAUKEE, WIS., Jan. 7—The Kelly-Springfield Tire & Rubber Co., New York, has established a branch house in Milwaukee, at 426 Jefferson Street, in charge of J. A. Glaspy. Another office will be maintained in the Bay Building, Madison, Wis.

—

Gillette Tire Co. Enlarges Plant

EAU CLAIRE, WIS., Jan. 7—The Gillette Tire Co. is contemplating the erection of 2 additional stories on its present 1-story main factory. To provide immediate warehousing and shipping facilities, the company has planned a 3-story concrete and brick building, 66 x 100, adjoining the main factory.

—

Reliance Truck to Move to Appleton

APPLETON, WIS., Jan. 7—Contracts will be awarded this week for the erection of the new Appleton plant of the Reliance Motor Truck Co., which is moving from Racine, Wis. The first unit will provide about 22,500 sq. ft. of floorspace and cost $50,000. The building will be ready for occupancy about April 1, at which time the equipment and machinery of the present plant in Racine will be moved. New equipment is being purchased for delivery early in April. The Reliance commercial car will be in regular production in Appleton about May 15.

—

Service Motor Truck Plans Additions

INDIANAPOLIS, Jan. 6—The Service Motor Truck Co., Wabash, Ind., which recently obtained a government contract for the manufacture of trucks, is planning the construction of two large additions to its plant. One of the buildings will be 75 x 200, and the other 50 x 400.

—

Hawke Transferred to Detroit

DETROIT, Jan. 8—Clarence B. Hawke will be associated with the sales division of the motor parts department of the Rich Tool Co., Chicago. His headquarters will be in the Detroit office.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Damrow Co. to Occupy New Plant

FOND DU LAC, WIS., Jan. 7—The Damrow Bros. Mfg. Co., Fond du Lac, Wis., manufacturer of sheet metal containers and stampings, will move into its new plant at Western Avenue and Brooke Street on Jan. 15. Because of the shortage and difficulty of obtaining supplies of sheet tin, the company has decided to install a complete rolling mill and will manufacture its own supply of sheets from the rough pig.

—

Cassidy Branches Out

NEW YORK, Jan. 7—The Edward A. Cassidy Co. has opened a Western branch office at 1716 Michigan Avenue, Chicago, with the idea of bringing its Western trade into close contact with the company officials. R. G. Ames, division manager for Chicago and surrounding territory, will have charge.

—

Changes of Capital

CLEVELAND, Jan. 3—The Ohio Rubber Co. has increased its capitalization from $400,000 to $500,000.

—

AKRON, Jan. 7—The Goodyear Tire & Rubber Co. has issued $15,000,000 of 8 per cent cumulative second preferred stock. The company is asking authority to increase its capital stock $50,000,000, half preferred and half common. If this is done, the authorized capital will be $100,000,000.

—

CLEVELAND, OHIO.—The Fred P. Brand Motor Co., increase of capital from $30,000 to $250,000.

—

COLUMBUS, OHIO—The Independent Tire Co., increase of capital from $10,000 to $50,000.

—

Capital Increases

COLUMBUS, OHIO, Jan. 5—The following are the capitalization increases in the past week: Buckeye Motor & Cycle Co., Akron, $15,000 to $50,000; Dayton Reliance Tool & Mfg. Co., Dayton, $20,000 to $50,000; Fred P. Brand Motor Co., Cleveland, $30,000 to $250,000; Steubing Truck Co., Cincinnati, $5,000 to $80,000.

—

Bigsby to Investigate Factories

WASHINGTON, Jan. 7—G. L. Bigsby, engineer for the Anderson Electric Co., has been loaned by his company to the Automobile Industries Committee, and will serve on the corps of engineers now employed by that committee for investigation of automobile and parts factories.

Haskelite to Build Grand Rapids Factory

GRAND RAPIDS, Jan. 5—The Haskelite Co., capitalized at $1,000,000 for the manufacture of special veneer airplane parts, is preparing to establish a factory near Fuller station. This company already has a factory at Ludington, Mich., but the main factory will be in this city. It is estimated that the industry will bring about 3000 persons into Grand Rapids.

—

Ford Producing 78,258 Cars a Month

DETROIT, Jan. 5—All rumors to the contrary, the production of the Ford Motor Co. still continues above normal. During the months of September, October and November a total of 234,774 cars have been manufactured, or an average monthly production of 78,258 cars. This has been done coincidently with the manufacture of Government material and unless subsequent Government orders materially decrease the production, the company will reach its schedule for the year totalling 900,000 cars.

—

Butler-Veith Takes Fageol Output

BERKELEY, CAL., Jan. 4—The Butler-Veith Co. has contracted for the entire truck output for the United States of the Fageol Co. A branch has been opened at 1628 Market Street, San Francisco, with W. A. Knuckey in charge.

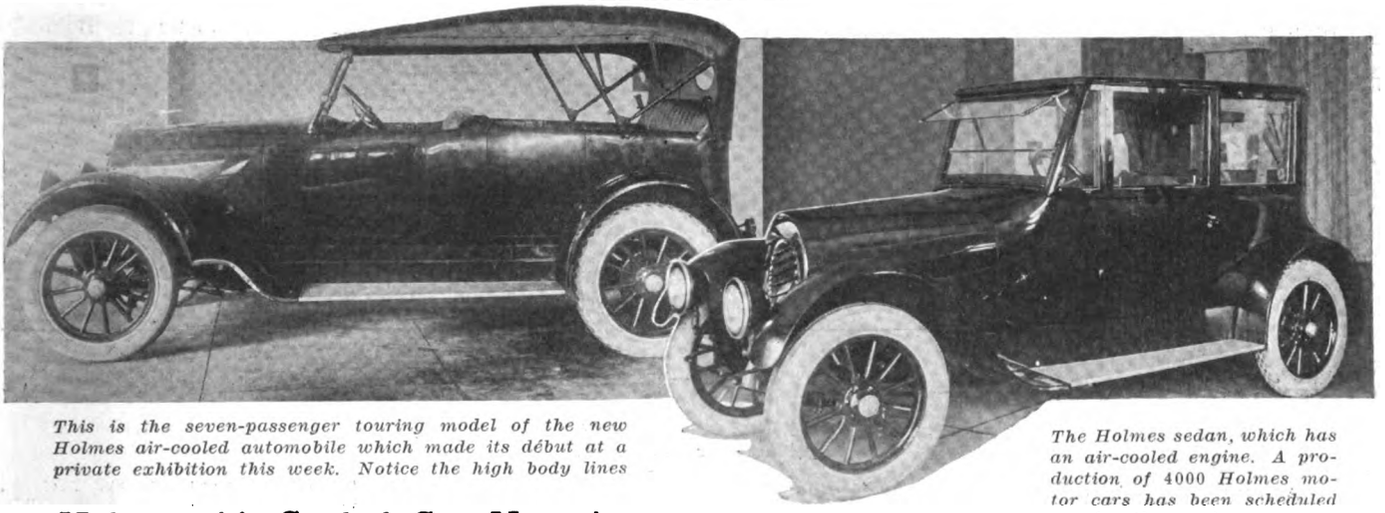
—

Flottorp Starts Propeller Production

GRAND RAPIDS, MICH., Jan. 5—The Flottorp Mfg. Co., manufacturing aircraft propellers, expects to make the first shipment this week. At present about 40 employees are working and it is expected that this will be increased to 250 when the full running schedule is reached.

—

Premier Motor Increases Force



INDIANAPOLIS, Jan. 6—The Premier Motor Corp. is making rapid strides to fill its Government contract for the manufacture of Liberty trucks. The working force is being increased rapidly, and officials of the company announced to-day that it would be necessary to employ at least 300 women to rush work on the contract.

—

Brewer-Mosel to Sell Wisconsin Tractors

SAUK CITY, WIS., Jan. 7—The entire output of the Wisconsin Farm Tractor Co. will be sold by the Brewer-Mosel Automobile Co., Madison, and an active sales campaign has been undertaken already. The Wisconsin company, which was organized in 1915, manufactures a kerosene tractor capable of drawing 4 plows and serving as a power plant for grain separators and other farm machinery.

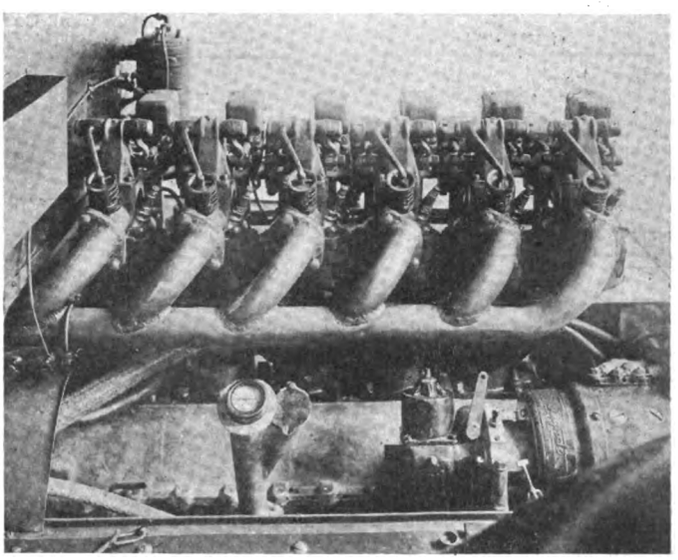
This is the seven-passenger touring model of the new Holmes air-cooled automobile which made its début at a private exhibition this week. Notice the high body lines

The Holmes sedan, which has an air-cooled engine. A production of 4000 Holmes motor cars has been scheduled for the coming year

Holmes Air-Cooled Car Now in Production

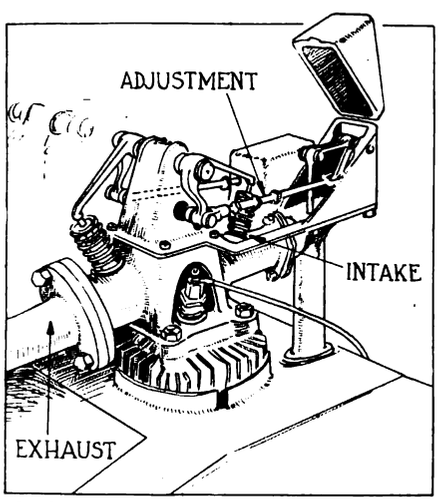
Canton Product Has Overhead Valves and Vertical Fins

AMERICA'S second air-cooled car, the new Holmes, about which there has been much speculation, quietly made its debut at a private exhibit this week. As was expected the design of Robert Holmes, formerly vice-president of the Franklin company and for seven years its chief engineer, the new car has a number of features which are the same in principle as those of the older ones, but differs considerably in the method of their working out.



This is the product of the Holmes Automobile Co., Canton, Ohio, organized about a year ago. A production of 4,000 has been scheduled for the year, with the first twenty cars coming through this month. The car appeared as a seven-passenger touring and a sedan on the immediate program, with a roadster to come through later. The price has not been fixed definitely, but is between $2,000 and $2,500.

The method of cooling which has characterized Franklin practice, that is by means of a draft of air induced by a suction fan and led around vertically finned and separately cast cylinders is incorporated in the Holmes car, but instead of having the air jacket around individual cylinders the Holmes has its air jackets inter-connected. The construction of the cylinders themselves is similar to the older type, but the Holmes has removable cylinder heads of dome shape carrying inclined valves, which are operated by a patented mechanism designed to compensate more fully for elongation and contraction due to changes in temperatures in the bush rods. The valve mechanism consists of a connection between bush rod and valve stem through two bell cranks and an adjustable linkage so arranged, that even with the maximum elongation of the push rod there is less than .001 in. variation in the distance between tappet and valve stem.



The use of the dome-shaped cylinder head into which the valves are set at an angle permits exceptionally large valves, particularly exhaust valves, and producing in addition to more power the more important factor with an air-cooled car, a cooler cylinder with minimum combustion chamber area. The removable head can be taken off by taking out four machine screws and one nut, which displaces the entire valve mechanism as a unit.

Details of the engine design aside from the valve mechanism and cooling arrangement include a six-cylinder, individually cast engine 3½ by 4½ in. Lubrication is pressure feed throughout by gear pump with oil leads to each main bearing. The crankshaft is drilled, carrying the oil to the connecting-rod bearing and oil is sprayed from these for piston lubrication so that the engine base is dropped.

The Sirocco type of induction fan, which is incorporated with the flywheel, draws the air through the louvres in the front and thence through an air jacket around all the cylinders instead of through individual jackets. This permits less space between cylinders, making a more compact engine with shorter crankshaft.

Standing Cars Must Be Lighted

BOSTON, Jan. 5—The Massachusetts Supreme Court has decided that motor cars standing by the side of the road at night must have lamps lighted the same as when being operated. James E. Henry left his car standing on the road in Malden at 8.30 p. m. May 3, 1915. He was arrested and found guilty in the lower court. He appealed from one court to another, taking the matter to the Supreme Court as a test case. The higher court now finds that he was guilty of operating his car without lights later than one-half hour after sunset. Judge Crosby, who wrote the decision, said:

"It is obvious that an automobile standing upon a highway under such conditions may be fully as great a menace to the safety of the travelers as if running upon the way, without lights. The word 'operated' is not as the defendant claims, limited to a state of motion produced by the mechanism of the car, but includes at least ordinary stops upon the highway, and such stops are to be regarded as fairly incidental to its operation."

International Harvester to Have New York Distributer

NEW YORK, Jan. 8—The International Harvester Co. hereafter is to be represented in New York. The Whiting Motor Co., which for the past 9 years has handled Mercer passenger cars, has been appointed International distributer for New York and Newark, N. J., territory. There will be a new 2-ton International truck brought out this month. The company will continue to handle the Mercer.

Calendar

ASSOCIATIONS

Feb. 4-7 — St. Louis, American Road Builders' Assn. Convention.

GENERAL

Jan. 11-16—New York, Convention, National Association Automobile Accessory Jobbers, Hotel Astor.

Jan. 16-20—World's Salesmanship Congress, Third Annual.

Jan. 29-31—Chicago, Annual Convention, Garage Owners' Assn. of Ill., Green Room, Congress Hotel.

SHOWS

Jan. 5-12 — New York Show, Grand Central Palace, National Automobile Chamber of Commerce.

Jan. 12-19 — Philadelphia, 17th Annual Show, Philadelphia Auto Trade Assn., Commercial Museum Bldg.

Jan. 11-19—Providence, R. I., R. I. Licensed Auto Dealers' Assn., State Armory, Percival S. Clark, Mgr.

Jan. 14-19 — Rochester, N. Y. Tenth Annual Exposition Park. C. A. Simmons, Mgr.

Jan. 16-25 — Milwaukee, Wis., Milwaukee Automobile Dealers, Inc., Auditorium. (First 7 days, passenger cars; last 3 days, commercial cars.) Bart J. Huddle, Mgr.

Jan. 18-24 — Des Moines, Ia., Ninth Annual Passenger Car and Second Annual Truck, Des Moines Automobile Dealers' Assn., Coliseum. C. G. Van Vliet and Dean Schooler, Mgrs.

Jan. 19-26—Detroit Automobile Dealers' Assn., Overland Bldg. H. H. Shuart, Mgr.

Jan. 19-26 — New York Motor Boat Show, Grand Central Palace, National Assn. of Engine and Boat Manufacturers.

Jan. 19-26—Detroit, Willis Avenue Overland Service Station.

Jan. 19-27 — Cleveland, Seventeenth Annual. Cleveland Automobile Show Co., Wigmore Coliseum. Fred. H. Caley, Mgr.

Jan. 19-26 — Montreal, Can., Montreal Automobile Trade Assn., Ltd., Almy Bldg. T. C. Kirby, Mgr.

Jan. 21-26—Manchester, N. H., Academy. Couture Bros.

Jan. 21-26—Scranton, Pa., Scranton Motor Trades Assn., Armory. Hugh B. Andrews, Mgr.

Jan. 21-26 — York, Pa., Queen Street Tabernacle, York Automobile Dealers' Assn.

Jan. 21-26 — Wilmington, Del., Hotel Du Pont.

Jan. 21-26—Buffalo, N. Y., Buffalo Automobile Dealers' Assn., Broadway Auditorium.

Jan. 21-26—Richmond, Va., Richmond Automobile Dealers' Association, First Regimental Armory. Henry B. Marks, Mgr.

Jan. 22-24—Montreal, Can., Convention of All Men Interested in the Automobile Industry in Eastern Canada.

Jan. 22-25—Oklahoma City, Oklahoma City Motor Car Dealers' Assn. Carhart Building.

Jan. 22-26—Baltimore, Md., Baltimore Automobile Dealers' Assn. and Automobile Club of Maryland, 5th Regiment Armory.

Jan. 22-26 — Oklahoma City, Okla., Oklahoma City Automobile Dealers' Assn., 701 No. Broadway. Roy H. Haun, Mgr.

Jan. 23-28—Allentown, Pa., Lehigh Auto Trade Assn., Traylor Motor Co.'s Garage. P. W. Leisering, Publicity Mgr.

Jan. 26-Feb. 2 — Chicago National Show, Coliseum and Armory, National Automobile Chamber of Commerce.

Jan. 26-Feb. 2—Chicago, Salon, Elizabeth Room of Congress Hotel.

Jan. 26-Feb. 2—Bridgeton, N. J., Bridgeton Auto Dealers' Assn. O. P. Riley, Sec.

Jan. 26-Feb. 2—Harrisburg, Pa., Capital City Motor Dealers' Assn. J. Clyde Myton, Mgr.

Jan. 26-Feb. 3—York, Pa., York County Auto. Dealers' Assn., Tabernacle, T. F. Pfeiffer, Sec.

Jan. 28-Feb. 2—Buffalo, N. Y. Buffalo Automobile Dealers' Assn., Broadway Auditorium.

Jan. 28-Feb. 2—Manchester, N. H., Academy. Couture Bros.

February — Greensburg Pa., Westmoreland Automobile Dealers' Association.

Feb. 2-9 — Minneapolis, Minn., Twin City Automobile, Truck Tractor and Industrial Exposition, Minneapolis Auto Trade Assn.

Feb. 5-9 — Kalamazoo, Mich., Kalamazoo Automobile Dealers' Assn., Armory.

Feb. 5-9—Binghamton, N. Y., Binghamton Automobile Dealers' Assn., Kalurah Temple. William M. McNulty, Mgr.

February — Peoria, Ill., Peoria Auto and Accessories Dealers' Assn. W. O. Ireland, Mgr.

Feb. 6-9—Lancaster, Pa., Automobile Trade Assn., Fidelity Bldg. R. W. Shreiner, Mgr.

Feb. 7-13—Portland, Ore., Ninth Annual Dealers' Motor Car Assn., Auditorium. M. O Wilhin, Mgr.

Feb. 9-16 — Bronx, N. Y., 2d Battery Armory, Bronx Automobile Dealers' Assn. D. J. Barrett, Mgr.

Feb. 11—Toledo, Terminal Auditorium, Toledo Auto Show Co.

Feb. 11-14—St. Louis, Mo., St. Louis Auto Mfrs. & Dealers' Assn. Robert E. Lee, Mgr.

Feb. 11-16 — Kansas City, Mo., Kansas City Motor Car Dealers' Assn., Convention Hall. E. E. Peake, Mgr.

Feb. 11-16—Kansas City, Mo., Third Annual National Tractor Show.

Feb. 11-16 — Toledo, O., Toledo Auto Shows Co.

Feb. 16-23 — Hartford, Conn., Hartford Auto Dealers' Assn. State Armory. B. F. Smith, Mgr.

Feb. 16-23—Albany, N. Y., Albany Auto Dealers' Assn. State Armory.

Feb. 16-24—San Francisco, Cal., San Francisco Dealers' Assn., Exposition Auditorium. G. A. Wahlgreen, Mgr.

Feb. 18-23—Syracuse, N. Y., Syracuse Automobile Dealers' Assn., State Armory. Harry T. Gardner, Mgr.

Feb. 18-23 — Nashville, Tenn., Nashville Auto Trade Assn., Hippodrome.

Feb. 18-23—Grand Rapids, Mich., Automobile Business Assn., Klingman Building. Ernest T. Conlon, Mgr.

Feb. 18-23—Newark, N. J., N. J. Auto Exhibition, Co. G, First Regiment Armory. Claude E. Holgate, Mgr.

Feb. 18-23—Des Moines, Ia., Des Moines Automobile Dealers' Assn., Coliseum. C. G. Van Vliet and Dean Schooler, Mgrs.

Feb. 18-23 — Springfield, Ohio, Springfield Auto Trades Assn., Memorial Hall. C S. Burke, Mgr.

Feb. 18-23 — Waterbury, Conn., United Shows Co.

Feb. 18-23—Duluth, Minn., Duluth Automobile Trade Association. John J. Lane, Mgr.

Feb. 18-24 — Des Moines, Ia., Ninth Annual Passenger and Second Annual Truck, Des Moines Automobile Dealers' Assn., Coliseum. C. G. Van Vliet and Dean Schooler, Mgrs.

Feb. 18-25 — Pittsfield, Mass., State Guard, State Armory. James J. Callaghan, Mgr.

Feb. 18-27—So. Bethlehem, Pa., Fourth Annual (cars 18-23; trucks 25-27). Coliseum. J. L. Elliott, Mgr.

Feb. 20-23—Quincy, Ill., First Annual, Armory. L. B. Bartlett, Mgr.

Feb. 23-Mar. 2—Brooklyn, N. Y., Brooklyn Motor Vehicle Dealers' Assn., 23d Regiment Armory. I. C. Kirkham, Mgr. Passenger cars Feb. 23-Mar. 2; Trucks Mar. 5-9.

INSURE YOUR RADIATOR

THE only way you can be positive that your radiator won't freeze up this winter is to use a non-evaporating, anti-freeze preparation. The present high cost of alcohol—its low boiling point—and quick evaporation make it impractical. Besides, you are asked to conserve the supply of alcohol for use in explosives.

Does Not Evaporate

Johnson's Freeze-Proof does not evaporate so one application is sufficient for the whole winter unless the solution is weakened by leakage of the radiator or hose connection, through the overflow pipe, or by boiling over.

JOHNSON'S FREEZE-PROOF

Johnson's Freeze-Proof should be used wherever you wish to prevent water from freezing—in automobiles, gas engines, tractors, electro-lighting and heating plants, traction companies, etc. One box will prevent 3½ gallons of water from freezing at 5° below zero. For lower temperatures increase the portion of Freeze-Proof.

Absolutely Harmless

Johnson's Freeze-Proof contains no oil and does not interfere with the cooling system. It will not injure rubber, cloth, packing, or metal of any kind. It does not rust or corrode any metal. Johnson's Freeze-Proof is economical and easy to use and it raises the boiling point of water 12° to 25°.

Johnson's Freeze-Proof is put up in packages containing 6½ lbs. net which retail at $1.50 each in the U. S. A. One package will protect a Ford from freezing at 5° below zero. For larger cars use two packages to protect to 5° below zero, and three packages to protect to 20° below zero.

Write for our new booklet, entitled "Keep Your Car Young". — We will send it to you free and postpaid. — The information in this book will enable you to greatly improve the appearance and the performance of your car.

PEER

The "Loafing" Range

TO PURR along in the consciousness of tremendous reserve force—

To be able to loaf smoothly behind retarded traffic and yet be able to dash ahead the instant there is an opening—smoothly—without hesitation—and quickly reach any permissible city speed—

That is the charm of the Peerless Eight in its "loafing" range.

To have in reserve rugged resistless power *at no expense until you use it*—that is the economy of the Two-Power-Range Peerless Eight.

For in its "loafing" range the Peerless is on half rations—consuming fuel so sparingly as to shame many a lesser powered six, even many a four.

Here is eighty horsepower which you can use with true economy in every-day driving—yet eighty horsepower which you can use with full effect when you need or desire it.

In Two Whole Years No Unsold Peerless

IN ITS second year, just ended, the Two-Power Range Eight, in spite of doubled production, again outsold the output of the huge Peerless factories.

Among the master cars of the day the Peerless Eight stands second to none in the respect and regard in which it is held by the motor-wise public.

Continuing as it has, the Peerless traditions of super quality in every detail, mechanically and artistically, this successor of a long line of master cars has out-performed them all.

With its two separate and distinct power ranges the Peerless runs the whole gamut of motor car performance.

It yields nothing to those master cars produced with the sole idea of realizing the ultra soft smooth performance so prized in ordinary, everyday driving.

Yet it has nothing to fear from those other cars of exceptional distinction which sacrifice the gentler virtues for resistless power and speed.

And it naturally out-performs at all points those cars of class whose sponsors have realized their ideal of the best compromise between the gentler and the more rugged virtues.

The Peerless dealer's three big advantages are demonstrable economical, superior performance, conceded super-quality and the lowest price among recognized master cars of the day.

The Peerless Motor Car Company, Cleveland, Ohio

Peerless

LESS

New Two Power Ranger Better Than Ever

IN TWO years of steady, uninterrupted, full capacity production during which the justly renowned Peerless engineering department has had the performance of thousands of these cars under constant critical observation, many mechanical and artistic improvements have been effected.

The unprecedented range of performance attained by the Two-Power-Range Eight has been measurably extended in both directions.

It is a smoother, more finished performer in its "loafing" range.

It is faster than ever, even more powerful in its "sporting" range.

It is notable among the cars of class.

From the standpoint of performance it stands today, more truly than ever, Peerless—all that the name implies.

And from the standpoint of low cost it is likewise without a peer in its class.

Eighty horsepower is not operated at so little expense in any other car.

And steady production in large volume, with exceptional resources and facilities, has enabled us to attain and maintain a price level hundreds of dollars below any of the other master cars of the day.

We offer dealers definite advantages. Have you, as a dealer, definite advantages to offer the manufacturer? If so, let's discuss opportunities for mutually profitable business.

The Peerless Motor Car Company, Cleveland, Ohio

80 horsepower, eight-cylinder motor—entirely Peerless-Built

Wheelbase 125 inches

35 x 4½ Cord Tires

Peerless platform rear spring suspension

Touring Car—seven passenger capacity—divided front seats

Fully equipped

Peerless
TWO POWER RANGE
Eight

The "Sporting" Range

TO TAKE a new lease on life and climb on with renewed courage when you would expect her to falter at so long and steep a grade—

To speed faster and yet faster after you thought she had delivered her final spurt—

That is thoroughbred performance—the kind that the "sporting" range of power makes possible in the Peerless Two-Power-Range Eight.

To reach her "sporting" range you have only to open her throttle wider to release her double poppets when a deep growl of brute power replaces the soft purr of her "loafing" range.

When you call upon the Peerless for feats of prowess of which few cars are capable, you get instant, willing, able response.

You need fear no contender no matter what "class" it may be able to show.

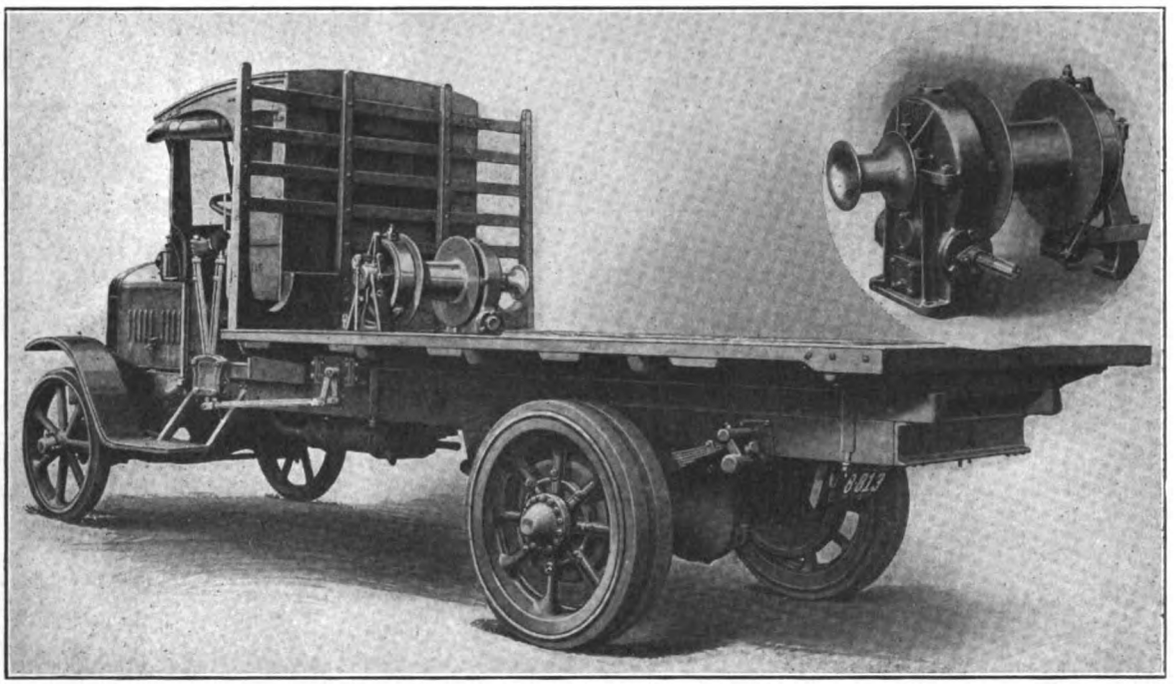
Comfort

¶ A car you'll want to live in. Fleet, buoyant, luxurious comfort for every passenger. Massive cushions and strainless ease. To its great springs and deep cushions, the Standard "8" adds its noiseless, throbless, uncomplaining whirl of machinery. Eight mighty cylinders pour their power into the short, rigid, perfectly-balanced crankshaft. The gears engage like velvet. You accelerate from speed to speed hardly conscious of swifter motion. ¶ Here is true beauty of performance. Not a trace of sidesway. Instantaneous getaway. You glide through the worst traffic without shifting from "high." Or mount a dismaying hill with robust acceleration without resorting to "low." ¶ Distributors and dealers in territory still open are invited to call on any of our representatives for a ride in this truly wonderful car.



Prices, $2450 to $4000.

A MOTOR TRUCK POWER WINCH BEARING THE NAME OF OTIS

This means that it is designed and manufactured by the same concern which for more than sixty years has developed and brought to its present state of perfection the building and installation of elevators and other hoisting apparatus.

It means, in short, unqualified satisfaction.

The use of power winches on motor trucks is no longer a matter of experiment; but is recognized as a time and labor saving method of the utmost utility.

The Otis Power Winch

is a step in advance. It makes the truck a more profitable investment by doubling its operating value and usefulness. It enables a small crew to accomplish quickly what a large crew accomplished laboriously. It enables companies to utilize their trucks at their maximum capacity with a minimum of time and labor. It represents modern, practical methods as opposed to obsolete, impractical ones. It represents speed as opposed to delay, saving as opposed to waste, unlimited range of operation as opposed to limited.

As a matter of good business you owe it to yourself to send for our fully illustrated descriptive booklet. It is an interesting book, containing many pertinent and convincing facts. *Send for this booklet today.*

ENCLOSED CAR BODY MODE

More beautiful and luxurious than ever before, have been pronounced the H & K body designs, in hardwood-framed steel, under active production at the works in Philadelphia.

Illustration shows the latest H & K Steel Body for the Paige Sedan. The daring yet graceful lines, luxuriously upholstered interiors, the smartness and individuality displayed in this work, equals that of the most expensive custom-made, and appeals to all lovers of the beautiful in automobiling.

Our great works at Philadelphia are engaged on the finest enclosed body work for several of the foremost cars of the country—reflecting the buyer's keen appreciation of a really valuable and enduring product, made entirely complete, ready for application to the chassis, and now being shipped in large quantities daily.

Suggestion is made for your engaging space here for producing your requirements in the most successful steel enclosed bodies; steel stampings of all kinds; complete cushion and back springwork, etc. Inquiries and drawings to the nearest office.

Hale and Kilburn Company

Philadelphia

New York *Washington* *Detroit* *London* *Chicago*

"While at the Grand Central Palace don't miss seeing the most unique and pleasing specimen of our 1918 enclosed body work—a limousine design for the Marmon car in aluminum, and embodying the very best appointments, blue-and-gold-fabric interior, and a beautiful blending of shades in the exterior color scheme. This example of our work is now in our extensive exhibit of enclosed bodies at the New York Show."

Silence Wins!

Thousands of Fine 1918 Cars Will Carry the Famous

Morse Rocker Joint Silent Chains

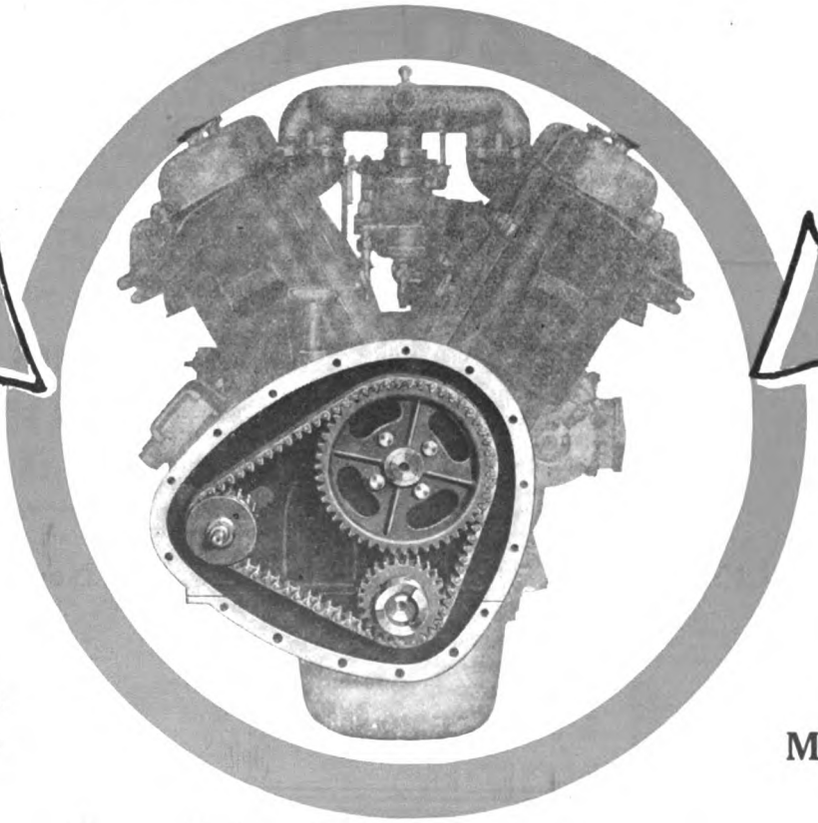
as standard equipment. The list includes almost every famous American make. They will dominate the high grade car field by right of quality and fine mechanical construction—but not by noise.

Silence is only one of the winning features of Morse Chains, but it is of high importance in the selling field. Modern car buyers are motor-wise and know enough to use their ears in judging a car. And engineers know that efficiency is silent. The noiseless operation of a Morse-equipped motor is a joy to the expert.

A Big Selling Factor

Morse Chains not only make a good car better, but do so in such an outstanding fashion that they make it an easier car to sell. Your dealers appreciate it when you equip with Morse. The first demonstration wins the sale. Further, Morse Chains are a strong talking point. They are known and noted as standard equipment on over 30 of the best known of America's quality cars. Morse prestige counts.

No More Front End Gears



The more advanced car builders have long since abandoned the use of gears to drive cam and accessory shafts. Gears have long been recognized as trouble breeders, noisy, easily stripped and hence the cause of endless discontent. You won't find them on the typical high grade "4," "6," "8" or "12." Find out what National, Cadillac, Stearns-Knight or Packard use. You'll find "Morse" on cars of these types. The superior principles of design and construction embodied in Morse Chains make them the logical choice of discriminating engineers. Will you have details?

A Square Path of Light—Twice the Lighted Area
A Safe, Glareless Light for over 500 feet ahead and 25 feet on either side

What the Dillon Means to You as a Dealer

As a dealer you are interested in turn-over. The goods you buy represent an investment of capital. The quicker you release that capital—the sooner the goods are moved—the more successful you are as a dealer.

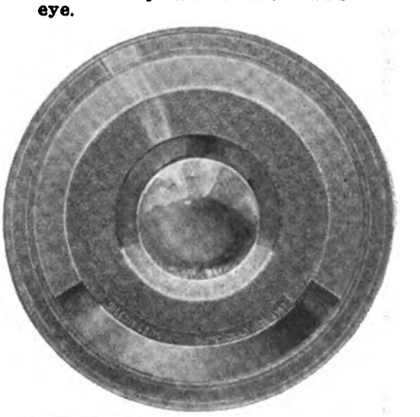
Consequently, you want only articles that move quickly, that require little effort to sell and only a minimum investment.

The Dillon Multi-Vision Lens is in that class. No lens possesses the innumerable selling points of the Dillon. No lens can claim, no lens can do, what the Dillon does.

The lens, the price, the demand, the advertising—everything—is to your advantage.

All sizes, from the smallest to the largest, sell for the same low price, $3.50 a pair. The Dillon advertising campaign is extensive and its plan unique. Every advertisement is made YOUR advertisement by **Otto Deeler,** a new trade character representing the auto dealer.

Get in touch with us—let us give you complete information about the Dillon Multi-Vision Lens and the selling co-operation offered



NATIONAL DISTRIBUTING BUREAU, INC.

Exclusive Distributors for the Dillon Lens

Oliver Building — Pittsburgh Penn'a

Dillon Lenses are manufactured by the
DILLON LENS & MFG. CO., Wheeling, W. Va.

THERE are three vital features of Dillon design, each of which contributes to the ultimate in light distribution. The mottled glass diffuses the light, while the clearer portion below illuminates the road at the side and front—hence a square path of light and, therefore, twice the lighted area. The bull's-eye in the center, a distinguishing feature of the Dillon Multi-Vision Lens, concentrates and magnifies the central beam of light below eye-level. These otherwise dazzling rays are scientifically neutralized, diffused and deflected from the clear glass immediately above the bull's-eye.

It Has Actually Happened!

The progressive members of the industry rose up and showed their strength, their foresight and the courage of their convictions.

The "Before New York Show" Issue of MOTOR WORLD carried *more advertising than ever before!*

Were You One of Them?

If so, you are doubtless represented by proper space in MOTOR WORLD'S Before Chicago Show Issue. You realize that the use of such space *more than doubles the effectiveness* of your advertising in the New York Show Issue.

If not, the Before Chicago Show Issue of MOTOR WORLD offers your last opportunity to be adequately represented—at the *most important merchandising season of the whole business year!*

Do Not Forget That—

These Dealers, Jobbers and Garagemen are now making up their minds as to what cars, parts and accessories they are going to carry, and which ones it will be to their interest to push, during the coming season.

This Issue goes to press January 12th. Your advertising "copy" should reach us earlier than that. Prepare it *now* and send it *at once.* This is the Last Call!

It Pays To Advertise In These Show Issues!

The large volume of advertising that has come and is still coming in to our New York and Chicago offices for insertion in the Big Show Issues of "Automotive Industries" and "Motor Age" speaks louder than words of the confidence that prominent Manufacturers and Distributors have in the actual money value of such advertising.

These advertisers are not "taking chances," or "trying their luck." They *know* what such advertising will do and *has done* for them.

This advertising is placed by men who have had experience in publicity and who know that the very foundation of successful business lies in proper publicity in the Trade Papers.

They know that these particular issues are of *vital* importance to advertisers in the automotive fields, for this is the beginning of the 1918 season and the impression made now is a deep and lasting one, and one that puts the whole season's business on a solid foundation.

If you are not represented by a thoroughly adequate advertisement in these issues you are making a mistake of omission that will cost you much additional effort and considerable profit later on.

Don't hesitate about this. It is not a question of ifs, ands or buts. The advertising value of these issues has been absolutely demonstrated year after year.

And this year is of exceptional importance. What you do—and what you don't do—will count more heavily for or against you than ever before.

Get Busy On Your "Copy" Today and Send It In At Once!

MOTOR WORLD

Before Chicago Show Issue

JANUARY 16, 1918

More than 20,000 people, Dealers, Jobbers, Garage and Repair men, who will buy, sell and recommend, in 1918, such articles as you are manufacturing or distributing, will read this issue

They will read it to get just the sort of information *you can give them.* They are looking for facts about motor cars, car parts, accessories and supplies.

An advertisement in this issue is a real necessity to a fully successful season for your goods. Your competitors know this and act upon the knowledge.

This issue goes to press January 12th. Don't take any chances—send in your "copy" now to our New York Office!

AUTOMOTIVE INDUSTRIES

Chicago Show Issue

JANUARY 24, 1918

Advertisements in this issue reach the final arbiters in automotive matters. Through its pages you can tell your story to the man to whom your prospects go for advice

This publication is *the* authority on automotive matters. It is the choice of the Engineer, the Manufacturer, the large, substantial Distributors, and of the technically well informed car owner.

This particular issue carries the extra importance and selling value of Show Time. It is filled with special information regarding cars and car parts in a complete form not found in ordinary issues. It is therefore read with unusual attention by *all* of its readers.

Get your "copy" to our New York office before January 20th!

MOTOR AGE

Chicago Show Issue

JANUARY 24, 1918

No other journal in the motor car field possesses so strong a selling influence as Motor Age

It reaches practically all motorists who are worth reaching, the ones who really react to advertising. This fact has been abundantly demonstrated by actual results.

This particular issue is the most important of the whole year. Advertisements in its pages, while they cost no more than for ordinary issues, are of more actual value to producer and distributor.

The Chicago Show Issue of Motor Age offers the advertiser a chance to hook up his story with the full power and effect of the Show in a manner and with a force that is impossible in any other way.

Get your "copy" to our Chicago office before January 20th!

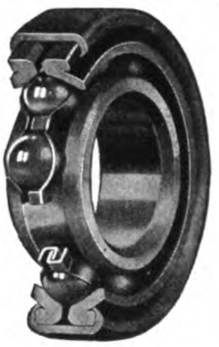
GALVANIZE RIMS AUTOMATICALLY IN MEAKER UNITS

Deposit a heavy, bright, uniform coating of pure zinc on all rims for your cars—the galvanized finish that looks good and is good.

Well galvanized rims are bright when they come from our machines and just as bright after they have made many thousand miles on your machines.

Superior Meaker Galvanizing will not cost you as much to produce as out-of-date, inferior, dark-colored, thin zinc coatings that do not even protect rims from rusting while they lie in storage.

Forward us a set of rims and felloe bands and we will give you some interesting figures.



MEAKER GALVANIZING COMPANY
1249 Fulton Street Chicago, Illinois

SCHATZ "UNIVERSAL" Annular Ball Bearing

Efficiency Accuracy

THIS internationally standardized combined radial and thrust bearing sustains successfully from 300% to 400% more thrust load than any other known annular bearing.

No pleasure car, truck or tractor will see sufficiently hard service to wedge or jam the balls in its "Universal" bearings.

Write for Catalog and Data Sheets

You will be interested in the unique features which enable the "Universal" bearing to lead the field in thrust capacity without adjustment and without impairment of annular efficiency.

"THE SUPER BEARING"

The "Universal" takes end thrust in either direction; has an inner race a third deeper than the average; an outer race in two units; a rivetless separator; a three area contact; a quality throughout that establishes a new high standard in the manufacture of ball bearings.

Automobile and Aircraft Instruments

ALIGHT AT NIGHT

WITHOUT WIRES, BATTERIES, SWITCHES OR ANY PERSONAL ATTENTION

MARVELITE

Provides continuous, practically permanent self-illumination of all instrument dials. It meets Government requirements. The basic light element in MARVELITE is radium (and radium only), the preparation containing a sufficient amount to generate a steady glow, lasting for many years.

MARVELITE is produced from formulas of the Schlesinger Laboratories, largest producers in the world of pure radium. It should not be confused with the short-lived phosphorus preparations which require exposure to light.

MANUFACTURERS: The luminous dial is of vital interest to the public, because of added safety and convenience. It brings the equipment of your machines up to date, and helps sell them. It is a necessity on aircraft, automobiles and motor boats. Insist upon having instruments that are "MARVELITED."

We will either sell the material to the manufacturer or apply it to his dials. Sample dials and hands prepared and estimates furnished upon request without charge.

The uses of Marvelite are too many and varied to be fully covered in this space. Send for Booklet No. 2 for information of importance to you.

AC Carbon Proof
For Fords, Overlands and Studebakers

How Often Must You Clean Your Plugs?
Ford—Overland—Studebaker Owners

The new *AC Carbon Proof Plug* will permanently rid you of plug trouble and keep your motor running on *all* cylinders *all the time.*

The Reason

A deposit of carbon on the smooth surface of the porcelain is what causes short circuit with ordinary plugs. With the AC Carbon Proof plug the porcelain is provided with a number of ribs having saw tooth edges which attain a sufficiently high degree of heat to burn away the carbon. This keeps the edges free from deposits and breaks up any possible short circuit.

Blankets won't help much if—

the oil you are using does not flow freely at Zero

SUPREME AUTO OIL flows freely at Zero

STARTS WITH THE ENGINE

THIS is most important during the Winter months. You should know whether the oil you are using "flows freely at Zero." All oils do not possess this feature—notably the paraffine-base oils, which thicken up under cold and often cause great damage to the motor.

The safe way is to ask for SUPREME AUTO OIL—it "Flows freely at Zero" and leaves less carbon, owing to the fact that it is a Southern Asphalt-base oil containing no paraffine to gum, stick or thicken.

For Sliding Gears That Grit Their Teeth—Use K-OO Special

NON-FLUID OIL

Quiets and protects the gears, and perfectly lubricates the ball and roller bearings in transmission. Does not harden in cold weather, so is safer to use than greases or gear oils which congeal, and through which the gears channel, thereafter, running bare of lubricant.

NON-FLUID OIL costs no more than common greases. On sale at all dealers—in orange-colored cans only. Write for free sample.

Hartford UNIVERSAL Joints

Established 1906

The Hartford Automobile Parts Co.
Hartford, Conn.

We are able to offer manufacturers universal joints manufactured by specialists in one of the largest plants in the world.

The wearing surfaces of HARTFORD UNIVERSAL JOINTS are hardened and ground, the grinding being accomplished by a specially devised machine whose use eliminates depressions or elevations so common in steel parts that have been simply reamed.

The reputation of your car demands the best universal joints that can be made, and we have them.

Steel for Service

Gears cut from

Solid Rolled Steel Blanks

and heat treated are very much superior to those made of any other material.

Gear cutters place "case hardened forged steel" gears cut from Carnegie Blanks at 500 as against 100 for standard cast steel gears.

These gears are most excellent for tractors and thousands are in use. Service and satisfaction go with them to the owners.

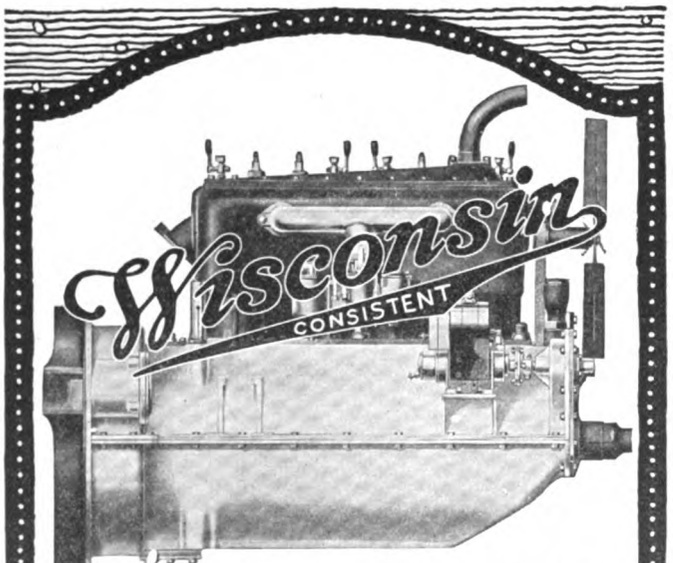
Save Money Without Sacrificing Appearance

In this time of nation-wide economy, are you finding ways of cutting costs—and still retain quality? One item of saving—and it's no inconsiderable part of motor equipment either—is

GLASS



We have a mighty acceptable substitute for polished plate; and whether you use it on closed cars, windshields, clock faces, oil gauges or what-not, you will find it optically perfect. It looks well, too—and of course it's very moderately priced.

Write us your requirements, and let us tell you why this glass will serve your needs so well, why it costs less—and all about it.

AMERICAN WINDOW GLASS CO.

World's Largest Producer

General Offices, Farmers' Bank Building
Pittsburgh, Pa., U. S. A.

PERFORMANCE

That's what the truck prospect is interested in most of all. If he knows your truck is powered with a Wisconsin Consistent Motor, a big step has been made in its sale. Wisconsin Motors are champions of the world on road and speedway—why not link their reputation to your product?

Write for specifications of different types and sizes.

Achievement

It takes Confidence of the staunchest type to launch a new business such as we launched a little more than two years ago, involving as it did the expenditure of hundreds of thousands of dollars in plant and equipment.

But we had confidence in the ideal which we had created, and that confidence is reflected in our achievement —in every glowing furnace and every ton of AGATHON steel they daily produce, and, best of all, in the enthusiastic satisfaction of our customers.

AGATHON Steels Will Serve Your Purpose Best

Russel Features

The power axle is entirely independent of the load-carrying axle, wholly relieving it of road and load strains.

The load-carrying axle is a one-piece round bar of heat-treated chrome nickel steel. The Russel Differential, Internal Gears and Pinion Gears are made in our own machine shops guaranteed by Russel reputation.

Russel brakes are exceptionally large and afford unusual protection to the truck on the crowded thoroughfare and steep grade.

Less complicated parts.

More efficient and reliable under all conditions of road or load.

More ground clearance.

Less dependent upon lubrication.

Operating cost less.

Assures more tire mileage.

—THAN OTHER TYPES

SLIPPERY PAVEMENTS. Horses falling. Horses helpless. Traffic retarded. It is inhuman; it is costly; it is bad business. And it is out of date.

I am the Motor Truck. I am busy, effective, resistless as usual. Slippery pavements mean no more to me than snow or mud because I am weather-proof and feeling-proof.

I am equipped with the Russel Internal Gear Drive Axle. I deliver maximum power to both wheels, close to the rims. My load I carry on a separate axle of solid steel. Therefore, I am surefooted, unfailing and uncomplaining. These things make masters of transportation.

Russel Motor Axle Company

AUTOMOTIVE INDUSTRIES
The AUTOMOBILE

Vol. XXXVIII
No. 4

NEW YORK, JANUARY 24, 1918

Twenty-five cents a copy
Three dollars a year

What Will You Do If You Can't Get Cars?

That Situation is Quite Probable With Dealers Who Do Not Make Early Arrangements for Territory

Never in the history of the world has there been so much money in circulation as there will be during the next twelve months.

The government program calls for a monthly expenditure exceeding a billion dollars. An appropriation of two hundred million dollars for railroad equipment is planned. Investors are to be guaranteed returns on their holdings. Farmers know there will be a certain and profitable market for all they can produce. There is evidence that wages are to be increased—in some lines the discussion mentions as much as 40 per cent.

Everyone knows what so much money in circulation does to the demand for automobiles. Add to that the growing needs of the nation for motor car transportation caused by the increased loads upon the railroads.

Now think how serious the situation promises to become because of curtailed production. This year's output will be at least 40 per cent under that of last year.

All the facilities of the Hudson factory that can be used to advantage for government work will be devoted to making army trucks and transmissions for army tanks. It leaves us with facilities for building 15,000 Hudson Super-Sixes.

Fifty thousand Super-Sixes, more built than of any other fine car, have been sold during the past two years. You can see how inadequate the number available this year will be.

We are merely meeting the minimum needs of our Distributors. They will first of all take care of their most loyal dealers. The eleventh-hour contractors may find it too late to arrange for deliveries.

Delayed decision on your part may deprive you of cars this year.

UTILITY
Protected Foot Rail
HEATER

Heating Core Gets Hot Enough to Burn or It Would Not Heat Your Car

Protector Shield Stays Cool Enough to Touch So It Cannot Burn Shoes or Robes

—*manufacturers*

It is as much a duty to equip your cars that are to be used in winter with a UTILITY Protected Foot Rail Heater as it is the duty of the contractor to specify a heating system in your home, factory or office.

Other manufacturers include UTILITY Protected Heaters in their specifications for patrons' comfort—all because UTILITY installation actually sells cars.

—*jobbers*

Over 200 new jobbers added to our list this year—many of them veterans who know the heater market from A to Z—proves the established demand for UTILITY Protected Foot Rail Heaters.

Experience shows that UTILITY is the car heater it pays to catalog and sell.

—*dealers*

The selection of UTILITY Protected Heaters by the majority of jobbers in the United States, is their recommendation to you. UTILITY Protected Heaters are in their hands in force—favorites of the trade-wise men who know. UTILITY Protected Heaters sell. They have every advantage from price to service. Once in your stock, they move.

—*car owners*

Taking into consideration the matters of health, comfort, cleanliness, simple installation and operation, and actual warmth—UTILITY Protected Heaters, in service, answer every sanitary heating requirement at lower cost, and with better results than are obtainable from any other source.

—*prices*

No heating expense whatever is involved. Once installed UTILITY Protected Heaters work free.

UTILITY Protected Heater	$15.00
UTILITY Jr. Protected Heater for Fords	7.50
UTILITY Front Seat Heater, for Maxwells, Chevrolets, Fords and Front Seat Installations in all other cars	10.00

Prices west of Rockies:

UTILITY Protected Heater	$16.00
UTILITY Front Seat Heater	10.75
UTILITY Jr. Heater	8.00

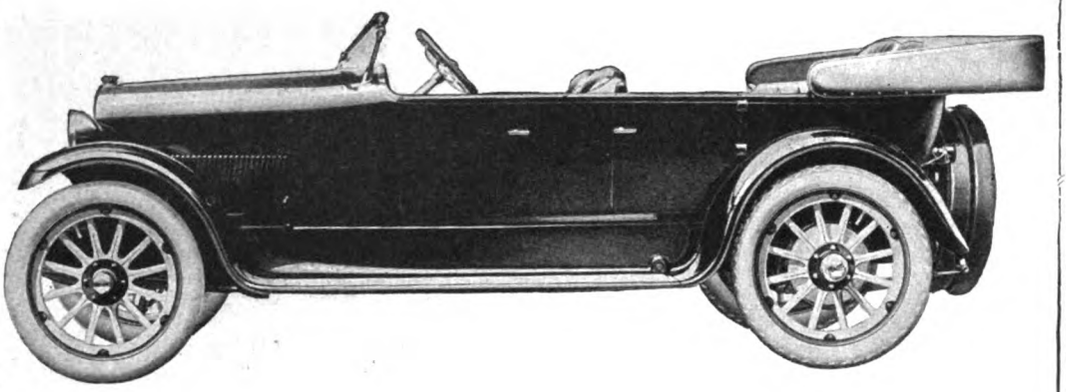
THE ONLY WAY TO SAVE GASOLINE!

Cover your Radiator until the red fluid in your Boyce Moto-Meter rises to the bottom of the white circle.

ENGINEERS have been telling us for years that the only way to save gasoline is to operate the motor at a high temperature.

If this is not done 30 to 40% of your gasoline goes out the exhaust pipe unburned and wasted.

Don't blame the manufacturer of your car for poor gasoline mileage. His duty was at an end when he supplied you with a Boyce Moto-Meter.



Cover your radiator until your Boyce Moto-Meter reads Summer Average. Then and then only will you start saving gasoline—simple isn't it?

THE MOTO-METER CO., Inc., Long Island City, N. Y.

BOYCE MOTO METER

CASE SIX

The Case Idea
—and Yours

AT the New York Show there was widespread attention paid to the "All Feature" principle as exampled in the New Case Six. In this one car men found combined all the attractive features, and at a price lower than expected.

Mechanical excellencies are properly combined with beautiful design.

Here is complete pleasure and utility value, without untimely extravagances.

And as men go over the Case Six point by point they note the basic fundamentals of good car building, combined as never before. They realize that Case Engineers have created the finest Case Car ever offered.

Go over the specifications yourself. Note the tried and proven features. And when you examine the car, see how they are proportioned exactly, and how they are designed to make a harmonious and unified whole.

Every Case dealer knows that he offers in this New Case Six the finest car on the market for the money. Over-values are apparent. The customer is bound to be enthusiastic.

Family Model, a 7-Passenger Touring Car, color dark blue, $1875; Sport Model for four people, color periscope green, $1875; All-Seasons Model, Springfield Type, for 7 or 5 people, color dark blue, $2375.

If you haven't come to know this car yet, and our profitable proposition, write immediately. An opportunity such as this is rare.

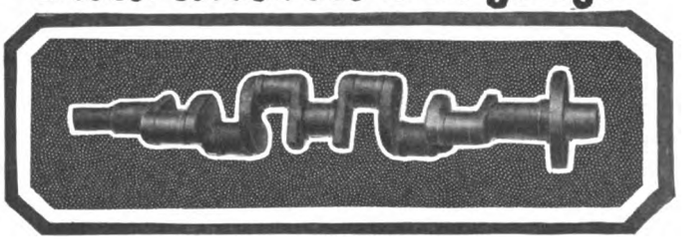
WYMAN-GORDON

Making Sure



HERE IS A CORNER of the Wyman-Gordon laboratory where samples of every steel billet brought into our yards are tested to *make sure* that they are up to the Wyman-Gordon standard.

"MAKE SURE" IS THE WATCH-WORD of Wyman-Gordon. Our guarantee certifies that we have made sure to the full extent of our ability.

THE HIGH QUALITY of Wyman-Gordon Products extends beyond the quality of steel used and the character of workmanship involved. It includes designing, the capable handling of manufacturing problems submitted to us, the cooperation offered by a staff of experts who have concentrated upon this particular subject.

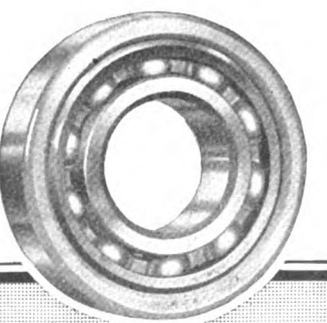
THE SCHATZ "UNIVERSAL" Annular Ball Bearing

Letters from users of the "Universal" prove that **it leads the field internationally** in **safety** and **carrying capacity** and that it **triumphs** over the **hardest** service conditions.

Takes **300%** to **400%** **more thrust load** than any other known annular bearing. Takes end thrust in **either direction without adjustment** and **without impairment of annular efficiency.**

"The Super Bearing"

INNER race one-third deeper than the average and held to curvature only 4% greater than the curvature of the balls.



Outer race generated on two integral cups or race rings with space between to distribute radial load and to prevent binding strain under thrust load.

Separator free from rivets, rivet holes and distance pieces. It consists of two interlocking units and is sufficiently flexible to accommodate itself to changes in the axis of rotation of the balls.

Races and balls made from the highest quality of high carbon chrome crucible alloy steel to a specified analysis.

Raw material, parts in process and **finished product** are so rigidly and persistently inspected that the "Universal" has established a new standard of quality for ball bearing manufacture.

The "Universal" is a self-contained, combined radial and thrust bearing **internationally standardized** and **interchangeable.**

Engineers of motor cars and parts or of any other mechanism with rotating members should write for catalog and data sheets.

VOL. XXXVIII NEW YORK—THURSDAY, JANUARY 24, 1918—CHICAGO No. 4

Late Exemption Notices

Delay Production of War Orders

Many Firms Closed Friday and Saturday But Opened Monday—War Truck Factories Not Exempted—Illinois Tractor Makers Exempted But Wisconsin Not Exempt—Airplane Work Halted Friday and Saturday—Automobile Production Stopped—Dealers and Service Stations Closed

NEW YORK CITY, Jan. 23—While the entire automotive industry displayed an excellent spirit of patriotism in almost universally obeying the letter of the Fuel Administrator order closing factories for 5 days, there has been very general criticism in the way the order was carried out.

Unfortunately, exemption notices were not well timed, and great numbers of factories engaged in the manufacture of airplane engines and parts were closed all day Friday and all day Saturday, because the exemption notices did not reach them until late Friday night and it was impossible to get the working forces of the factories together for Saturday.

This was particularly true in such centers as Detroit, Cleveland, Indianapolis, Toledo and Flint. For example, Ford, which is one of the largest manufacturers of war parts, was closed down Friday, and practically closed all day Saturday. The injury and delay of such a closing down affected not only the Ford plant but others making aircraft parts for the reason that Ford supplies the cylinders for many makers.

Due to lack of proper notification with regard to exemptions, the tractor industry in Illinois and in Wisconsin suffered seriously. Many tractor makers received their exemption notices in time to begin work Saturday, but their factories had closed on Friday. In Wisconsin the J. I. Case Co., one of the largest tractor makers, was closed down completely and in all probability will have to remain closed during the 5 days as the Wisconsin State Fuel Administrator did not exempt the factories the same as did the Illinois administrator. In Minnesota the tractor interests were closed by the Fuel Administrator's orders.

One way in which the exemptions issued by the Fuel Administrator failed to carry was in connection with those firms manufacturing parts for the standardized war trucks of the Quartermaster's Depart-

Digitized by Google

ment. While makers of aircraft parts and tractor parts received exemptions none were received by the makers of engines, axles and other parts for the war trucks.

In Milwaukee the shut-up of industries is almost complete, only five or six out of 2300 industries remaining in operation; even the Wisconsin Motor Mfg. Co., which is working on government work almost exclusively, received its exemption from the War Department too late and it was closed Friday and Saturday, but renewed work Monday morning.

In Cleveland, the closing up situation was made worse by the fact that the street railway company was put on a Sunday schedule, so that thousands of workers were hours late in reaching the factories that had been given permission to work.

Many factories engaged on government work were not given exemption notices in time, and they were closed during Friday and Saturday. Peerless, which is making 10 trucks a day for the British government, was closed during the 5-day shut-down. Stearns, engaged on aviation engine parts, did not receive its permission to go ahead until Tuesday, so that it virtually lost all 5 days. Standard Parts has only half its men at work, although it is on government orders. The Marvel Accessories Co., working on airplane parts, could not receive an exemption, although it wired for one; it shut down for 5 days and used the time to install machinery.

Manufacturing in Indianapolis was practically suspended by the rule, and on Monday only one or two concerns were exempted. Nordyke & Marmon got an exemption order on its aviation work only. Premier, which is manufacturing F. W. D. trucks, was also exempt. All other factories were closed.

The Detroit situation was very serious. Ford laid off 35,000 men; Packard 8000; Cadillac 6000; Hupmobile 12,000; Continental 3000, and Timken 5000.

The greatest criticism from Detroit was that the exemption lists did not come with the order to shut down. The order was issued so late Wednesday night in Washington that the morning papers were not able to carry it as were the daily papers in the eastern section of the country. Detroit feels that the economy of coal is not at all commensurate with the loss to the industry by the shutting down order of the Fuel Administrator.

Fuel Order Closed 90% of Detroit's Plants

More than 200,000 Men Temporarily Out of Work—Comparatively Little Coal Saved by Shut Down

DETROIT, Jan. 19.—One bitter thought overspreads all others in connection with the effect of the fuel edict throughout Michigan, Ohio, and the Middle Western territory. This is, that in spite of the hundreds of thousands of men thrown temporarily out of work, in spite of industries temporarily paralyzed, very little fuel is really being saved. It is necessary to heat the plants to save them from destruction by freezing, and this takes a large percentage of the coal ordinarily consumed. In some of the big plants not over 10 tons a day are being saved by the order.

The general attitude of manufacturers is expressed in the words, "As patriotic citizens we must obey the edict of the government regardless of our personal opinions." The factories at once closed down, some of them operating a short time Friday until the order was recognized as being authoritative. Friday night telegrams were sent out to plants engaged on war contracts, but these were received too late in most instances, with the result that many had a hard time getting their organizations together Saturday to go on with the work.

Plants like Packard, Ford, Cadillac, Fisher Body, General Aluminum & Brass, Detroit Copper & Brass Rolling Mills, and the American Car & Foundry Co. were included in the exemptions announced by the Fuel Administration in Washington late Friday. All of these companies have one or more departments on important war work, and these departments alone are in operation today. There are others, however, doing war work which were still closed in all departments this morning. These included local plants working on parts for the Liberty trucks, such as Continental and Timken.

About 75 per cent of Detroit industries were shut down Friday, and on Saturday morning virtually 90 per cent of the city's industries adjusted themselves to the schedule imposed by the Fuel Administrator.

In accordance with the protest meeting held at the Board of Commerce Thursday afternoon, about forty shops, employing large numbers of men, went to work as usual Friday morning, but when an order was sent out by Governor Sleeper declaring that it was unpatriotic to disobey the edict, and that the State would enforce it, these also fell in line.

The greatest confusion is being caused by the delay in announcing exemptions. Many of those engaged in different branches of war work are expecting their exemptions hourly, but cannot afford to pay their organizations and hold them at the plants in anticipation of these orders. It was not until very late Friday afternoon that the fuel administration admitted officially that important war work is not affected by the order, and gave out a list of hundreds of factories that may continue work on government contracts only during the 5-day period.

Local factories engaged in war work telegraphed the fuel administration offices in Washington and also to the Washington representatives, when they had them, asking for definite rulings on these war contracts, with the result that the exemption list was hurried to some extent. Automotive products covered in the plants exempted in a list prepared by Secretaries Baker and Daniels included aircraft and aircraft parts, Signal Corps equipment, electrical supplies, and certain steelwork. The army trucks were not mentioned, although word is being expected on them any minute.

Willys-Overland closed except in the departments doing government work. The Elmira plant is running night and day, and the Elyria plant is also going ahead with its airplane work. The number of men laid off by the Willys-Overland Co. is 8000. The coal saving of this company amounts to about 200 tons a day.

Practically the same conditions apply to Buick, where all but the aircraft men are laid off, making a total of

Digitized by Google

about 12,000 employees out of work for the 5-day period. This company uses normally 600 tons of coal a day, of which 42 per cent will be saved through closing. The general coal situation in Flint is probably as bad as it is anywhere in the country. There are 4000 families practically without coal, and there is no coal anywhere near the city, and no cars en route. The schools have been closed for a week and the coal taken from the cellars and placed into the bins of private users. This company has voluntarily reduced its production by closing its plant over a week ago to conserve fuel to meet the serious situation obtaining in Flint.

Ford started Monday operating in the departments where government work is under way, the most important of this being the department concerned with the manufacture of cylinders for the Liberty aircraft engines. This highly important work was closed down with the rest of the factory because the Ford company did not get its exemption order until late Friday night, when it was too late to get the force together to start work again Saturday. In saving of coal the 5-day shutdown of the Ford company will mean about 60 carloads, or 12 carloads a day. The normal consumption is from 17 to 18 carloads per day.

The number of men thrown out of employment in Detroit alone is approximately 200,000. These men will not be paid during the layoff period, so far as is known by any of the companies, although one or two still have the matter under consideration. To give an idea of the number of men affected by the order, the Ford company has laid off temporarily 35,000 men, Willys-Overland 8000, Buick 12,000, Studebaker Detroit plant 3000, Continental 3000, Cadillac 6000, Packard 8000, Timken (both plants) 5000, and Hupmobile 12,000.

Some of the companies making motors and feeding back the power developed by these motors on test back into the lines really lose coal instead of gaining it by the closing order. A rough estimate of the coal saved by some concerns is: Hupp Motor, 10 tons a day; Packard, 35 tons a day; Studebaker, 150 tons a day; Timken, 100; Buick, 250; and Willys-Overland, 200. Figures from other companies are not available.

Illinois Tractor Makers Escape Shut Down

CHICAGO, Jan. 19.—The tractor industry in Illinois is the only portion of the motor industry where manufacture is not greatly restricted in this territory by the heatless-day order. According to an exemption ruling to-day, manufacturers of farm implements and agricultural tractors in the State are permitted to operate without interruption during the remainder of the five fuelless days and on the fuelless Mondays, as long as production is confined to orders for spring delivery.

Inasmuch as all of the more important tractor makers in the State have orders for spring delivery far ahead, the new ruling will permit them to resume operations, which have been suspended since yesterday.

So far as known now, tractor makers in other States are not so fortunate. In Wisconsin, the State fuel administrator has not exempted the implement and tractor men. The J. I. Case T. M. Co., Racine, Wis., one of the biggest farm implement and tractor manufacturers, as well as being a car builder, has closed down completely so far as work inside the plant is concerned, and will remain so till Wednesday, and on the following nine Mondays, unless a ruling is received to the contrary.

The instance of the Case T. M. Company is typical of larger concerns in many industries. This concern, though it is not making anything directly for our Government, is making the machines which increase the production of foodstuffs. Also it is making thousands of tractors for our Allies. At this time it is sending 700 carloads of tractors to Europe. Its 4500 men are idle, except those that can be used in clearing away snow and loading and unloading cars on its sidings.

Car and truck manufacturers who are not doing any government war business are shut up completely. Most of the concerns in this territory, however, are doing some Government work on war materials, trucks particularly, and are operating those portions of their plants devoted to the production of war orders. The remainder of their plants are closed. The Nash Motors Co., which is making war trucks, is operating the part of the plant solely devoted to U. S. orders, and has closed the rest. Velie is doing likewise, though 800 of its 1200 men will be idle during all of the heatless days. Root & Vandervoort, Moline, makers of the Moline-Knight, are devoting 85 per cent. of their facilities to war work, yet are closed down completely, and will remain so throughout the heatless days, unless they receive exemption orders.

Mitchell and Studebaker are closed to-day, and whether they remain so will depend upon rulings of the national or State fuel administrators. Both are working on government contracts.

One Milwaukee Plant Exempt

MILWAUKEE, WIS., Jan. 21—With the exception of the Wisconsin Motor Mfg. Co., every passenger and commercial car engine and parts factory in Milwaukee and vicinity was entirely closed for 5 days, throwing more than 7500 men out of employment. The Wisconsin Motor Co. closed with others Friday, but later received permission from the War Department to resume Monday morning to hasten Liberty engine production. Only five or six out of 2300 industries are in operation. All garages closed tight Monday. The loss of wages of 100,000 workmen is regarded as the worst result. The order is generally characterized as too arbitrary, considering peculiar local conditions, and hardly justified. No instances of violation are reported. The general effect is rather depressing.

Here, as in other cities, the exemption orders were received in many cases too late to permit the various factories to take proper advantage of them.

Indianapolis Industry Suspends

INDIANAPOLIS, Jan. 21—Industry in this city and central Indiana is all but suspended as a result of the enforcement of the federal Fuel Administrator's five days' closing. The Premier Motor Corp., which is manufacturing motor trucks for army use, is the only plant that has been in operation to-day, this company having received word from Washington Saturday to continue in operation.

Nordyke & Marmon, which is manufacturing airplane engines and milling machines in addition to automobiles, was the first company in the city receiving orders from the Fuel Administration to continue operations, but the order related solely to a continuance of the aviation and milling machinery departments.

The plants of the Cole Motor Car Co., the Stutz Motor Car Co., the National Motor Car & Vehicle Corp. and the Empire Automobile Co. have been closed, only enough heat being provided to keep automatic sprinkler systems from

Digitized by Google

freezing. All automobile plants in central Indiana that are not engaged in manufacturing supplies for the Aviation Department, or which are not making trucks, are not in operation.

Officials of the companies, although realizing that they have been compelled to sustain a serious loss, are not complaining over the order, although its issuance is universally condemned. The chief difficulty from the Fuel Administration's act is expected to be increased freight congestion, which, it is believed, will embarrass the motor industries considerably within the next few weeks.

Cleveland Shut Up Tight

CLEVELAND, OHIO, Jan. 22—Cleveland has been shut down tighter than may have been anticipated even by Fuel Administrator Garfield. When the shutting down process began the interdependence of industries asserted itself in a striking manner and the shutdown became tighter than was intended.

In this situation the street car company played an important part. On Monday it put on what it said was a Sunday schedule, it not having been directed to do otherwise. The result was that schools were an hour late in opening, thousands of workers were late in arriving at shops that had permission to keep open, and the public arrived at an almost riotous frame of mind as the packed street cars filed by without stopping. At one corner the crowd pulled the trolley pole off and forced its way aboard.

During this trying period motor cars and trucks came partially to the rescue. Taxicab companies did yeoman service.

Some shops with government work could get no reply from Washington or elsewhere, so shut down. In some cases exemptions arrived too late to be of value. The city determined to live up to the order unless explicitly instructed to the contrary, and the result was a shutdown tighter even than a normal Sunday.

Peerless, which is making 10 trucks a day for the British Government, is closed tight for the five days. Even its offices were closed Monday.

White closed Friday and Saturday, but opened up on government work Monday when an exemption was received. Chandler is closed tight and has moved part of its offices to parlors in the Hollenden Hotel.

Winton has government work on lighting sets, but is shut for the five days because it could get no order to the contrary. It expects to keep its offices open Mondays hereafter if possible.

Stearns is almost entirely shut down for the five days. To-day it got permission to work on its airplane parts contracts. It is hauling coal on trucks to keep open.

The Warner & Swasey Co., which is making gun fire control instruments, is working a third of its men. One thousand are out of work. Its exemption was not received until Friday. It uses 15 to 20 tons of coal a day and has about 100 tons on hand.

The Standard Parts Co., which is making truck and airplane parts, has from 800 to 1000 men out of work. It has about 1500 employees.

The Marvel Accessories Co., whose shop is making airplane parts, sent a 92-word letter to Fuel Administrator Garfield, but got no reply, and is using the five-day period to install additional machinery. A few of the factories have supplies of coal. Many are working from day to day.

Newspapers in this section state to-day that the five-day shutdown seems to have done little good so far as getting coal to Ohio's industries is concerned. The same applies to coal for home consumption. Most of the factories are not paying their men for the lost days and not many see any chance of regaining the lost time.

The public attitude is that the order should be obeyed first and talked about afterward. There is also a feeling that the public should be let to know a little more of the inside situation when such drastic measures are stated to be necessary. A strong sentiment seems to be rising in favor of a shutdown in passenger traffic if such would help the situation. This was recommended Monday by Hugh Chalmers at a meeting of Ohio dealers.

A continuance of winter weather has been a handicap.

Minneapolis Hard Hit

MINNEAPOLIS, Jan. 21—Automobile, tractor and accessory factories closed five days in Minnesota with few exemptions and tire and repair shops and oil stations to-day, in addition to smaller automobile factories at St. Cloud, Luverne and Duluth. In Twin Cities closures are as follows: Ford Motor Co., 600 men; H. E. Wilcox Motor Co., 300; Wilcox-Bennett Carbureter Co., 100; Pence Automobile Co., 200; Maxwell branch, 40; Chevrolet and Willys-Overland, small forces.

Tractor companies in cities and suburbs have about 4000 men, of which perhaps 1700 are exempt, including employees of Minneapolis Steel & Machinery Co. and Emerson-Brantingham Co.

Repair shop and oil stations are allowed to do emergency work. About 200 oil station men and 150 tire repair men are out and 2000 repair shop employees. The automobile industries seem to regard the day as a regular holiday, but tractor companies regret setback on their seasonable product, requiring one extra day to get cold shops working again. This applies also to tractor accessories, on production of which output of finished tractors depends.

Kansas City Little Affected

KANSAS CITY, MO., Jan. 21—No manufacturing industries are closed here so far by the Fuel Administration order.

The Fuel Administrators of Kansas, Missouri, Arkansas, Oklahoma, Nesbraska and Iowa are in conference to-day in Kansas City. All say that in these states all industries apparently can be taken care of, but amusements, saloons, office buildings and retail stores are being restricted.

Partial List of Companies Exempted

FOLLOWING is one of the early and partial lists, showing some of the concerns which have been exempted from the Fuel Administrator's order:

For the Manufacture of Aircraft and Signal Corps Products:

A. C. Clark Co.	Chicago
Packard Motor Co.	Detroit
Ford Motor Co.	Detroit
Lincoln Motor Co.	Detroit
Trego Motors Corpn.	New Haven
Nordyke & Marmon Co.	Indianapolis
Union Switch & Signal Co.	Swissvale, Penn.
Pittsburgh Model Engine Co.	Pittsburgh
Willys-Overland Co.	Toledo
Wright Martin Aircraft Corpn.	New Brunswick
Aeronautical Engineering Co.	Long Island City
General Motors Corp.	Detroit
Curtiss Aeroplane and Motors Corp.	Buffalo
Thomas Morse Aircraft Corp.	Ithaca
Fisher Body Corp.	Detroit
Dayton Wright Airplane Co.	Dayton
Standard Aeroplane Corp.	Elizabeth
Cutler Desk Co.	Buffalo
Rubay Co.	Cleveland
Engel Aircraft Co.	Niles, Ohio
Lewis Spring and Axle Co.	Chelsea, Mass.
W. H. Mullins Co.	Salem, Ohio
National Gauge and Equipment Co.	La Crosse, Wis.
U. S. Gauge Co.	Sellersville, Penn.
Julius King Optical Co.	New York City
Taylor Instrument Co.	Rochester
National Cash Register Co.	Dayton
Sperry Gyroscope Co.	Brooklyn, N. Y.
American Radio and Research Corp.	New York City
American Steel and Wire Co.	Trenton
Bausch & Lomb Optical Co.	Rochester
Hartzell Walnut Propeller Co.	Piqua, Ohio
West Woodworking Co.	Chicago

Digitized by Google

Flottorp Mfg. Co.	Chicago
John A. Roebling Sons Co.	Trenton
Western Electric Co.	New York City
Western Elect. Instrument Co.	Newark
Eastman Kodak Co.	Rochester
Splitdorf Elec. Co.	Newark
Wyman Gordon Co.	Worcester, Mass.
American Propeller Co.	Baltimore
Astoria Veneer Mill & Dock Co.	Long Island City, N. Y.

For the manufacture of emergency navy contracts:

Curtiss Engineering Corp.	Garden City, N. Y.
L. W. F. Engineering Co.	College Point, N. Y.
Aeromarine Plane & Motor Co.	Keyport, N. Y.
The Burgess Co.	Marblehead, Mass.

For the manufacture of products for Shipping Board:

General Electric Co.	Erie, Penn.
General Electric Co.	Schenectady
General Electric Co.	Lynn, Mass.

For emergency fleet orders and emergency Government work:

Bethlehem Steel Co.	Steelton, Penn.
Bethlehem Steel Co.	S. Bethlehem
Bethlehem Steel Co.	Sparrows Point
Midvale Steel & Ordnance Co.	Nicetown, Penn.
Midvale Steel & Ordnance Co.	Coatesville, Penn.
Midvale Steel & Ordnance Co.	Johnstown, Penn.
Lukens Steel Co.	Coatesville, Penn.
Carnegie Steel Co.	Pittsburgh
Crucible Steel Co.	Pittsburgh
Crucible Steel Co.	Harrison, N. J.
La Belle Iron Works	Steubenville, Ohio
Otis Steel Co.	Cleveland
Lackawanna Steel Co.	Buffalo
Illinois Steel Co.	Chicago
Jones & Laughlin Steel Co.	Pittsburgh
Donner Steel Co.	Buffalo
Inland Steel Co.	Indiana Harbor, Ind.
Central Steel & Iron Co.	Harrisburg
Republic Iron & Steel Co.	Youngstown
Brier Hill Steel Co.	Youngstown
Corrigan, McKinney & Co.	Cleveland
Forged Steel Wheel Co.	Butler, Penn.
Whittaker-Glassner Co.	Portsmouth, Ohio
Youngstown Sheet & Tube Co.	Youngstown, Ohio
Alan Wood Iron & Steel Co.	Conshohocken, Penn.

For the manufacture of "gas masks of the box respirator type":

B. F. Goodrich Co.	Akron
Goodyear Tire & Rubber Co.	Akron
Mechanical Rubber Goods Co.	Cleveland
C. Kenyon	Brooklyn
Nashawanna Mill	New Bedford, Mass.
Wamsutta Mill	New Bedford, Mass.
Sayles Bleacheries	Saylesville, R. I.
Hero Mfg. Co.	Philadelphia

For the manufacture of important forgings:

Bethlehem Steel Co.	South Bethlehem
Midvale Steel Co.	Nicetown, Penn.
Hydraulic Pressed Steel Co.	Cleveland
American Car and Foundry Co.	Detroit

Forgings for Destroyers:

Allis-Chalmers	Milwaukee
Camden Forge Co.	Camden, N. J.
Erie Forge Company	Erie

Miscellaneous:

Detroit Gear & Mch. Co.	Detroit
McCord Mfg. Co.	Detroit

Urge Permanent Highways Paralleling Railroads

Highways Industries Association Fosters Movement to Supplement Usefulness of Rail Carriers

CHICAGO, Jan. 21.—By telegram.—At the organization to-day of the Highways Industries Association, an organization which gives promise of much activity, the consensus of opinion was that this country must build and maintain permanent highways alongside of and paralleling our main trunk railroad lines, so as to supplement the movement of freight and passengers by the railroads with the transportation of these by automobiles and motor trucks.

To do this, superefforts must be made to connect up the disjointed sections of such highway systems as are in existence, and our road activities should be along such a national line rather than along a promiscuous, disjointed system of building in different States secondary highways which are not of primary importance during the war.

The main object to-day is to build and maintain these national systems of highways, which would preferably parallel our main trunk lines, as these, in the majority of cases, are the necessary channels of transportation.

One of the points of greatest interest brought out at the meeting was the announcement by James I. Blakeslee, fourth assistant postmaster general, who is in charge of the rural postal system, that if plans work out as expected there will be motor-truck parcel post within a short time under operation by the Government between all principal points.

One complete system which will be in operation within the next 60 days, according to these plans, is a route between Chicago, Indianapolis, Louisville, Nashville, Chattanooga and Atlanta, connecting with a similar route between Portland, Me., and New Orleans.

Organization of the Highway Industries Committee was one of national importance, as it brought together representatives from the Government as well as road machinery and material concerns with highway organizations, and State highway officials of the country. Over 150 delegates who were present represented 1500 plants with a combined capital of $4,000,000.

The objects of the organization, as outlined in the call to the meeting are:

To assist co-operation with all governmental agencies, both State and national.

The co-ordination of the highways with other transportation agencies of the country.

To encourage the development of highways that will advance the economic life of the nation and stimulate their use in such manner as to facilitate and cheapen the transportation of food, raw materials and finished products, to the end that our highways may be of maximum service in the transportation of the nation.

S. M. Williams of the Gramm-Bernstein Company, Lima, Ohio, was elected president; A. R. Hurst, Wisconsin State Commissioner of Highways, first vice-president; Leon Gardiner, New York, second vice-president; and S. T. Henry, Washington, D. C., third vice-president.

Secretary and treasurer are to be appointed by the directors. Headquarters will probably be in Chicago or Cleveland.

Crude Oil Production Increased 29%

Increase from Wells 196,905 Barrels Per Day Over Output During 1916—Daily Capacity Now 1,085,455 Barrels

WASHINGTON, D. C., Jan. 23.—From official figures given out by the Bureau of Mines, the supply of crude oil for the calendar year of 1917 increased 29 per cent over that of 1916. This meant a daily increase of crude from the wells of 196,905 barrels. The daily averages for the 2 years are:

	Bbls.
1916 Daily average.....	674,849
1917 " " (first 6 mos.).....	796,106
1917 " " (last 3 mos.).....	871,774

These are reassuring figures in spite of the fact that there has been a scarcity of certain tiling or tubing for new wells, and in some places a shortage of labor for the sinking of wells.

While the production of crude has shown a great increase, there has been a growing on the storage supply of manufactured gasoline, and between June 30 and Sept. 30, a 3-months' period, the stored stock of gasoline was drawn on to the extent of 77,217,782 gal. While the supply of gasoline was thus drawn upon the supply of kerosene on hand increased during this period to practically the same extent, the exact gain being 68,493,824 gal.

The report from the Bureau of Mines shows that on Sept. 30 there were 234 refineries in active operation with a combined daily capacity of 1,085,455 barrels.

In the period between June 30 and Sept. 30 the difference in the amount of stocks of crude oil on hand at the refineries was caused by 11,000,000 barrels of pipe-line stocks being reported as refinery stocks on June 30, but not so repo rted Sept. 30.

The tabulation herewith shows the stocks on hand at the different refineries on July 31, Aug. 31, and Sept. 30 and June 30.

The outputs of the different refineries for the first 6 months of 1917 show a daily average of gasoline of 6,763,-457 gal. The total output of gasoline during the period was 1,224,182,157 gal.

The daily average of kerosene during the same period was 4,333,764 gal. Total kerosene production for the first 6 months was 784,411,291.

Quartermaster To Buy 5000 Class A Trucks

Between Five and Seven Makers To Get New Kind of Assembly Contracts Early in February

WASHINGTON, D. C., Jan. 19—The Quartermaster Corps will be in the market for 5000 Class A War Trucks early in February and has arranged a new scheme for placing contracts. Probably between five and seven different manufacturers will be given the assembly jobs.

Under the plan of contract devised a list of at least four and not more than seven parts makers will be made for each of the following assemblies:

Engines	Wheels
Axles, front and rear	Radiator assembly
Transmissions and controls	Springs
Clutches	Gasoline tanks, fenders, hoods and other sheet metal work.
Electrical equipment	Lamps
Universal joints and propeller shafts	Tool equipment
Steering gears	Carburetor and other accessories
Frames	
Dash assembly	
Seat assembly	

Complete sets of drawings and parts lists will be sent to each of these parts makers and each will be provided with a schedule of quantities ranging from 1000 to 3500. The makers will submit bids by mail within 10 days after receipt of prints, to Col. Drake, Quartermaster Corps, Washington, D. C., and all bids are to be f.o.b. factories. Maximum prices are to be submitted by parts makers to truck assemblers when quotations are asked by assemblers.

Government May Buy Tools

Costs of tools, jigs and fixtures are also to be submitted and the Government will have the option of purchasing any sets of these tools and fixtures at the conclusion of the contract, subject to a suitable depreciation.

The Engineering department of the Military Truck Production Section of the Quartermaster Corps will furnish any necessary weights, etc., of parts specified in drawings.

Parts makers are being advised by letter that 5000 Class A trucks will be ordered for delivery in July, August and September and that these trucks will be purchased by the Government from the truck makers completely assembled and that all parts will be purchased and furnished complete by truck makers.

Inspection to Be Rigid

Van Dyke prints and lists of specifications are mailed with the letters to the parts makers, the Van Dykes being marked "for estimate only." The Quartermaster Corps reserves the right to make inspection of any units furnished in the trucks either at point of manufacture or as a completed unit.

Bids found acceptable from parts makers will, if the company is satisfactory as regards financial condition, capacity and organization, be so rated and the company will be placed on an approved list of companies to be submitted to the truck maker to aid him in preparing his total bid for completely assembled trucks. Bidders are informed that prices submitted to the Government will be maximum in comparison to prices later furnished to truck makers who secure assembly contracts. The Government does not guarantee the financial responsibility of any truck maker or truck assembler to whom goods are furnished by parts makers.

Distribute Cost of Tools

Complete sets of tools, jigs and fixtures are to be made up for this work and estimated prices to be submitted in connection with bids on material, and the Government is to have the option of the purchase of these with reasonable depreciation at the expiration of the contract. The cost of these dies is to be distributed pro rata on an estimated order for 2500 parts. If a parts maker's contract for parts falls short of 2500 the Government will pay for the pro rata difference; if the order is above 2500 the tool cost will be estimated on the quantity above that number.

Parts makers receiving Van Dykes and letter invitations to bid are requested to wire at once, if interested, to P. W. Tracy, Supervisor of Parts Plants of the Motor Transport Section, 1421 Eye Street, Washington, D. C., stating if bids are to be made.

Invite Makers to Bid

Truck makers and assemblers are to be notified by letter that contracts for 5000 Class A trucks will be let shortly and invited to submit bids according to blue prints, lists of specifications and bills of materials to be provided by the Government.

Completed trucks or separate units or parts of units are to be subject at all times to inspection and rejection by the inspection division of the Motor Transport Section.

A minimum of 750 trucks and a maximum of 2000 trucks will be alloted to any one maker. Truck makers are to purchase all units and deliver them completely assembled to be accepted after final inspection by the Quartermaster Corps. The lists of approved parts makers will be given all assemblers by the Government, but no guarantee of responsibility of these makers is made, these being subject entirely to the supervision and inspection of the truck assembler.

In cases where the truck maker is also the maker of certain units, upon application, survey of his plant will be made, and if found satisfactory he will be placed upon the list of parts makers for those units he is best suited to make.

Complete sets of tools, jigs and fixtures made for this work are to be estimated in price and submitted with assembly bids. The Government retains the option of purchasing these with reasonable allowance for depreciation at the expiration of the contract. The cost of the dies is to be distributed pro rata on an estimated order for 2000 trucks, and if the order falls short of this figure the Government will pay for the pro rata difference.

A list of units and selected parts makers is sent each assembler and it is expected that parts not mentioned in the list are to be secured by the truck assembler without suggestions from the Government as to sources of supply.

Should Telegraph Acceptance

Truck makers and truck assemblers are requested to telegraph acceptance of invitations immediately to Christian Girl, Chairman of the Motor Transport Section, 1421 Eye Street, Washington, D. C.

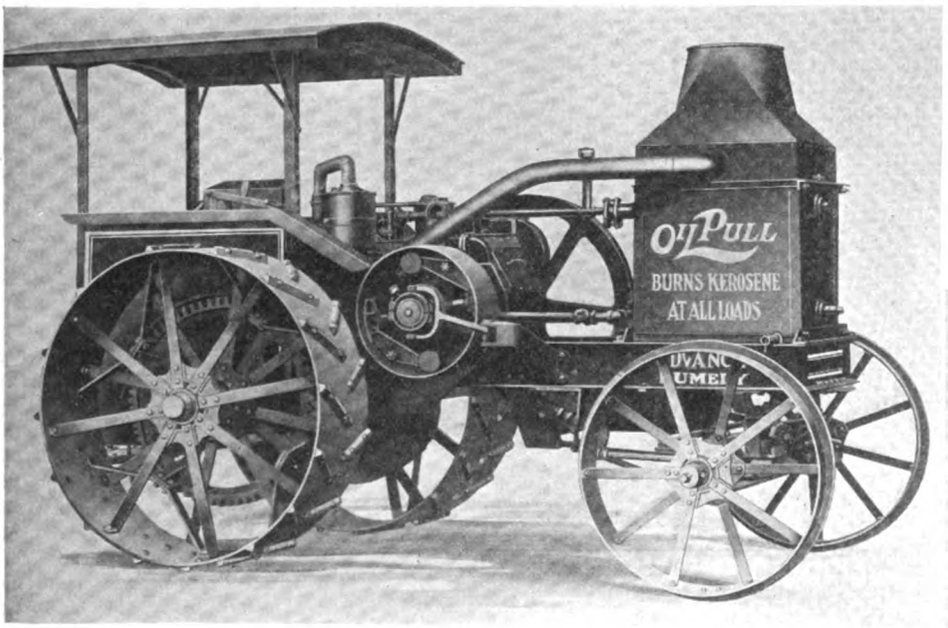
All bids are to be open and not sealed, to secure a selective service of trucks much like the selective service of men for the army.

As far as possible tools, jigs, etc., are to be limited to three sets on all major units and less on minor units and the Quartermaster Corps reserves the right to direct the number of sets of tools to be made at its expense.

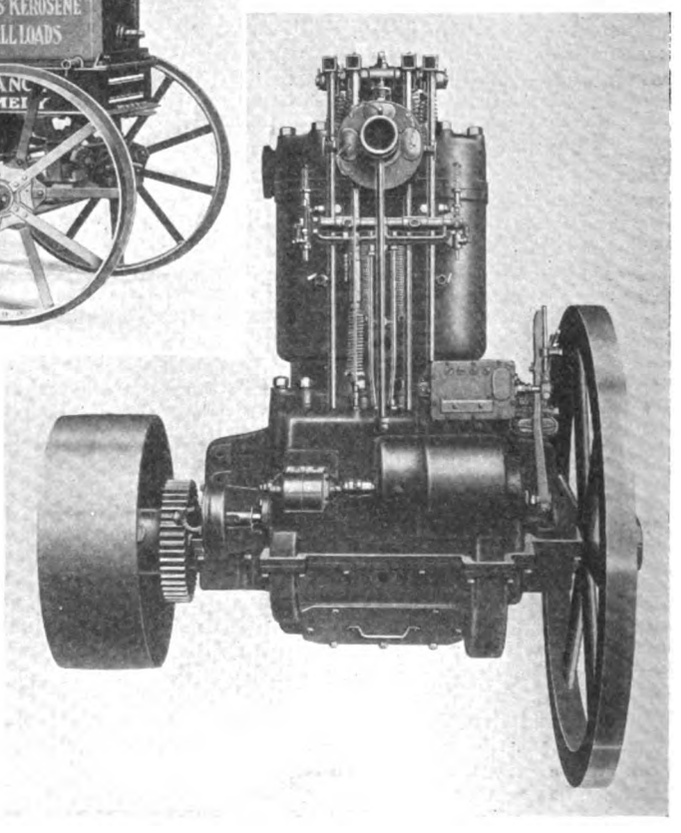
The Government reserves the right to reject any source of supply or any bid.

It is estimated that probably only five or six truck makers will be awarded the full amount of assembly contracts to thus avoid the delay and confusion arising from wide distribution of numerous small contracts.

Conference of Truck Makers



A meeting of the truck assemblers and truck makers who are interested in this business will not be called until after blue prints and specifications have been sent to the parts makers and detailed specifications are completed for the entire truck. Following this it is expected that truck makers and assemblers will be asked to submit bids for final decision within 15 days after the meeting.



It may be possible that this meeting will be eliminated by sending the makers who display their interest the necessary information and data and then calling only for a final meeting to submit bids.

Rumely Adds Smaller Tractor Model

Has a Rating of 14-28 H. P. and Burns Low Grade Fuel—Engine of the Low Speed, Two-Cylinder, Horizontal Type, Oil-Cooled and Governor-Controlled—All Spur Drive with Cushion Springs in Differential Drive Gear

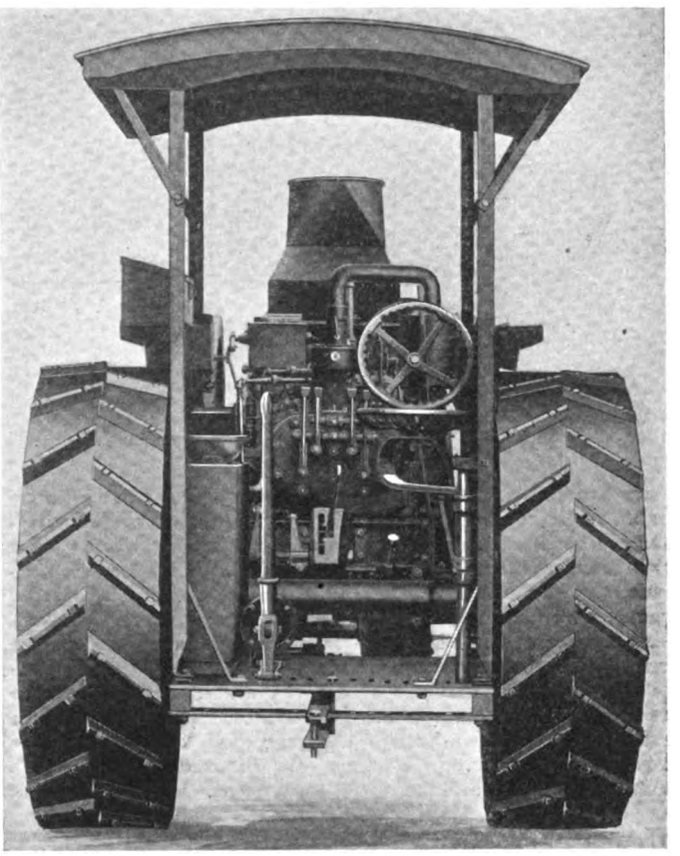
On left: A general view of the Rumely 14-28 tractor. Below: Plan view of the horizontal two-cylinder engine

RUMELY tractors employing the Secor system of burning low-grade fuel, which are manufactured by the Advance-Rumely Thresher Co. of La Porte, Ind., have long occupied a leading position in the tractor field. Heretofore they have been built in large sizes only, but, recognizing the demand for a small tractor suitable for moderate sized farms, the company has recently added to its line a new model having a rating of 28 hp. on the belt and 14 hp. at the drawbar. This model, like every other one put out by the company, is guaranteed to successfully burn not only every grade of kerosene sold in the United States and Canada, but also fuel oils and distillate free from earthy matter. While the new tractor is spoken of as a small one, it is really a rather fair sized machine, for with all supplies on board, ready for work, it weighs no less than 8700 lb., and it is guaranteed to pull up to five 14-in. moldboard plows, to turn over 14 acres of ground in a 10-hour day, and to handle on the belt a 24-in. separator fully equipped.

The two cylinders of the engine are cast in a single piece, but the head is separate. With a bore of 7 in. and a piston stroke of 8½ in., the engine delivers its rated power at 530 r.p.m. For the purpose of securing balanced turning the two pistons are connected to a two-throw crankshaft with the two crank pins 180 deg. apart. To further improve the balance of the engine, balance weights are secured to the two short crank arms. Each piston is provided with four diagonally split rings above the piston pin and with an oil scraping ring at the lower end. It is not necessary to disconnect any piping in order to remove the cylinder heads. The valves are operated by means of push rods extending along the top of the cylinders and by means of tappet levers provided with means of lubrication.

The camshaft is driven directly from the crankshaft by a spur pinion and gear. A small gear driven from the camshaft gear operates the flyball type of governor and the low tension Bosch magneto. On the camshaft at the opposite end from where the driving gear is located there is another gear used for operating the circulating pump. All bearings on the crankshaft are 3¼ in. in diameter. They are provided with split bushings for easy adjustment. The crank pin bearings measure 3¼ x 3¼ in. and the main bearings

Digitized by Google



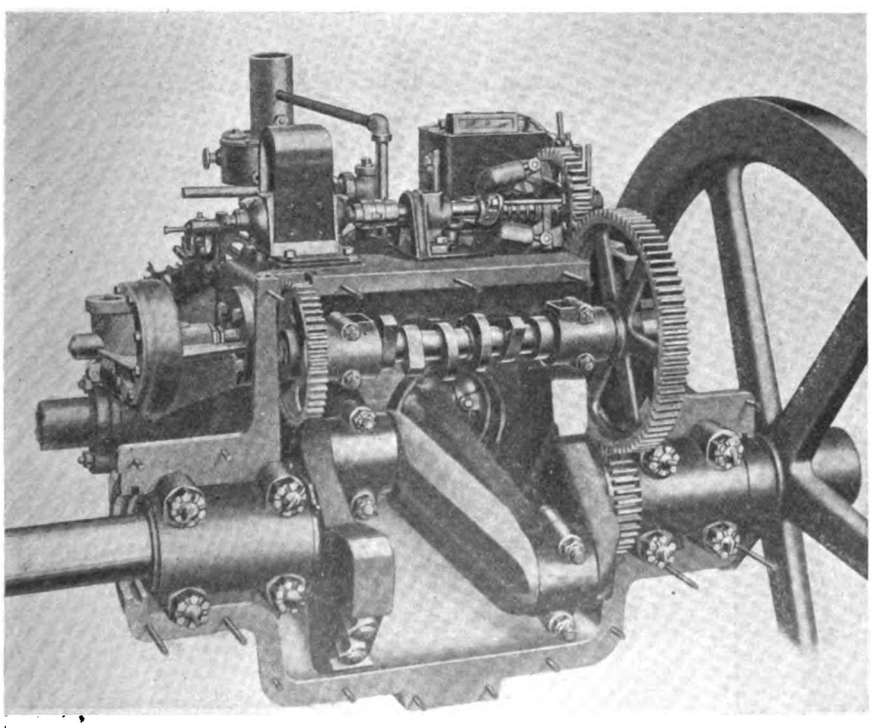
3¼ x 7 in. (flywheel end) and 3¼ x 8 in. (clutch end) respectively. The crankcase is of cast iron and is split in a vertical plane through the crankshaft axis. That portion of the crankcase to which the cylinder block is bolted supports the crankshaft bearings, the latter having caps secured by four bolts each. By removing a cover plate on the outer half of the crankcase any minor adjustment can be made. Only five gears are used for driving the camshaft and the various accessories, and all of these are fully inclosed and operate in oil. The camshaft driving pinion is located on the crankshaft inside the main bearing at the flywheel end.

As with other kerosene burning tractors, it is necessary to start on gasoline. The fuel tank has a capacity of 31 gal. of kerosene and 3½ gal. of gasoline for starting. The Secor-Higgins carbureter is used, and a sectional view of same is shown herewith. It will be seen to have two horizontal nozzles with a number of outlets each. One of these nozzles is for the kerosene and the other for the gasoline. One butterfly valve is located above the nozzles and permits of increasing the suction at will. The other butterfly valve, below the nozzles, serves for throttling the engine. With the Secor system water is injected into the cylinders to prevent pre-ignition when running under heavy loads.

Ignition is by low tension or make-and-break sparks. The spark plugs are manufactured by the Rumely company itself. The magneto which furnishes the current is of Bosch make. By referring to the cut of the engine in which the outer part of the crankcase is removed it will be seen that there are six cams on the shaft. The two inner ones of these actuate the spark mechanism. The trip rods can be easily adjusted for timing.

Engine Oil-Cooled

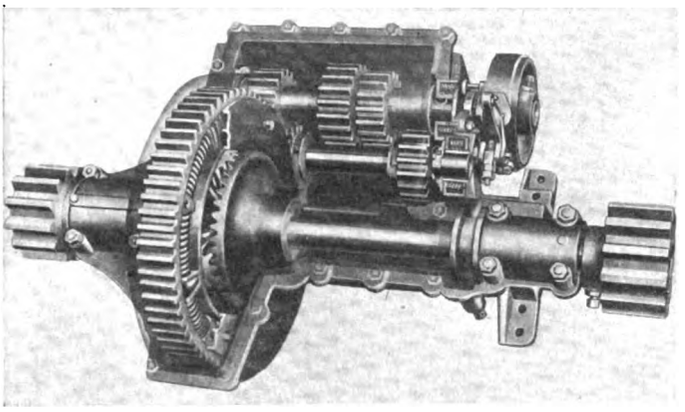
One of the features that undoubtedly adds to the success of the oil burning system is the use of oil cooling. Owing to the fact that mineral oil has a very much higher boiling point than water, it is possible to operate the engine cylinder at a much higher temperature with oil than with water cooling. The radiator is of the vertical type, of square cross-section, and is located at the forward end of the tractor. The capacity of the cooling system is 18 gal. No fan is required, and the power consumed in operating such a fan is therefore saved. With oil cooling the cylinder walls can be maintained at a temperature well above the boiling point of water. There are also other advantages connected with the use of oil for cooling. Oil will not freeze in the coldest winter weather, and as the oil never approaches its boiling point in the cooling system, it will not be lost by evaporation, and consequently needs not to be replenished frequently. Oil cooling is claimed to be particularly superior to water cooling when operating at low output, as in that case it is difficult to keep the cylinder wall temperature up.



Rear view of tractor showing arrangement of controls

Lubrication of the engine is effected partly by a mechanical oiler and partly by splash. The oiler with its sight feeds may be plainly seen on top of the engine crankcase in one of the cuts.

An extension of the crankshaft carries the belt pulley, which is 23 in. in diameter and has a face width of 8½ in. At 530 r.p.m. this gives a belt speed of about 3200 ft. per minute. This pulley is ordinarily loose upon the shaft, but can be secured thereto by means of the friction clutch. The clutch is of the expanding sector or shoe type, comprising two shoes operated by means of a shipping lever. The expanding members are counterbalanced so that centrifugal force has no effect on them. As the clutch is located inside the belt pulley and near the outer edge of same, it is easy to adjust it. Only one adjusting device is provided.



Transmission Two-Speed

The transmission is of the sliding pinion type and affords two forward speeds and one reverse. It is inclosed in a semi-steel casing made in two parts. Within this casing there are three parallel shafts, one receiving the power from the engine, the other one an intermediate shaft and the third the jackshaft or countershaft of the tractor, which carries at its end two bull pinions 4 in. wide each. The lower half of the transmission case is removable for purposes of inspection and adjustment. All

View of engine with outer half of crankcase removed

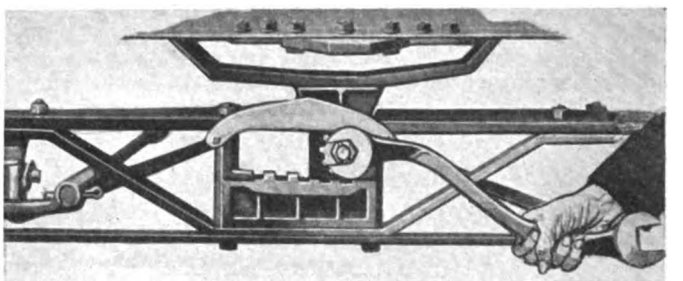
Digitized by Google

The two-speed and reverse transmission

gears are of steel, have machine cut teeth and run in an oil bath. A brake drum is located on an extension of the intermediate shaft outside the gear housing. This brake is lined with friction fabric and is operated by a pedal located convenient to the driver. It is said to be capable of holding the tractor securely on either an up or a down grade of any ordinary steepness, and of stopping it within its own length. All bearings on the transmission shaft are of the Hyatt flexible roller type. The two speeds are 2.1 and 3 m.p.h., and the reverse speed is 2⅝ m.p.h. In order to make possible the removal of the lower half of the gear case, the bearings are provided with caps. These caps are grooved to receive felt packing in order to make an oil-tight joint.

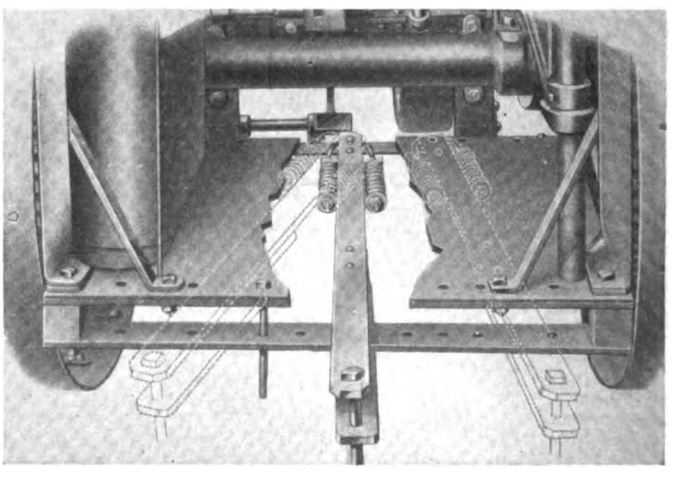
All Frame Members Straight

The frame is made of 8-in. heavy section channel steel, the side members and cross members being hot riveted together with angle plates. Each frame member is a straight piece, thus insuring the maximum strength. The rear axle, which is of high carbon steel 3¼ in. in diameter, is mounted in Hyatt high duty roller bearings at both ends of a tubular supporting casting of the cannon type. By the use of this type of rear axle housing a generous lubricant capacity is provided. The driving wheels are 56 in. in diameter and have a width of 18 in. They are of the built-up type with T-head steel spokes. Detachable grouters are used, which permits of the tractor being used for hauling and road work without damage to paved streets.



Rumely 14-28 tractor at work

The front wheels are 40 in. in diameter and have a width of 7 in. A built-up front axle is used, thoroughly braced. The steering gear is of the automobile type, the tractor being steered by means of a hand wheel, the shaft of which extends forward and carries a worm at its end. In order to permit the front wheels to accommodate themselves to sloping ground the front axle is pivoted at the center. To provide plenty of belt clearance, an arrangement is provided whereby the front axle can be moved laterally with respect to the frame whenever it is desired to use the tractor for belt work. This arrangement is clearly shown in one of the illustrations. On the pivot spindle of the frame there is a spur pinion which engages with a rack on the front axle. When it is desired to move the axle laterally, all that is necessary to do is to loosen a locking device on the axle and move the axle over by means of a wrench applied to a hexagon part on the pinion, which latter can be moved half a turn. This arrangement permits of the use of high front wheels properly placed, in connection with a belt pulley driven direct from the crankshaft.



Operator's Platform Low

The operator's platform is placed quite low, only a step from the ground. A canopy over the driver's seat is regular equipment and is so constructed that the operator has a clear view in every direction. An arm rest is provided at a convenient height. All of the control devices are within easy reach, including the gear shifting lever, the clutch lever, the steering wheel, the brake pedal and the carbureter and ignition hand levers. The gearshift lever works on a slotted quadrant, the control being of the selective type. The fuel tanks, which are calculated for a day's supply, are so located as to be easily accessible for filling.

The drawbar construction is referred to as of the swinging, spring cushion type. It is located directly below the platform and so designed that the hitch can be made at from 14 in. to 19 in. above the ground, with a wide range of lateral adjustment.

Arrangement for moving front axle sideways

The spring-cushioned, laterally adjustable drawbar

An Agricultural Power Unit*

Some Factors Governing the Design of a Small Tractor—Problems New to the Mechanical Engineer Involved—A Variety of Possible Types Considered

By Alan E. L. Chorlton

THE problem of providing mechanical power, to replace that of the horse, etc., in the most suitable and efficient form for the purposes of agriculture, is one of no inconsiderable difficulty, the guiding factors being such variables as the size of the farm, the class of land, the nature of crop, road transportation and the financial ones of first cost, annual charges, etc. The information relating thereto is so diverse, so variable and difficult to relate to actual fact (it seems more often a matter of opinion rather than fact) that the mechanical engineer investigating the problems on lines he is accustomed to finds himself at some loss where to begin, and is driven in the end, owing to this lack of precise information, to provide much of the essential data by actual experiment.

In this problem the difficulty of bringing together the agricultural expert and the mechanical engineer is a very real one. This difficulty is reflected in the tardy progress in this country of mechanical agricultural science, which, apart from the conservatism of the farmers themselves, has undoubtedly depended upon the cut-and-try methods so familiar in the past, and not upon scientific and technical research.

Though in the main the views held by farmers may be divided into two groups, those who favor a special power implement for each purpose and those who think a general purpose machine should be provided to deal with each and all, yet the problem should undoubtedly be considered, in the first instance, from the standpoint of capital expenditure and annual charges. The average farm in this country is comparatively small, and the farmer may find it financially impossible to purchse a special power-driven implement for each of his requirements, even should he be of opinion that such a policy is a desirable one. For example, if a light tractor were purchased for plowing alone, then a power unit would be needed for threshing, while on the road provision must be made for the mechanical power required for transport. A fourth power unit may even be required for other purposes, thus, a first cost of say £350 per unit might be increased approximately to £1,050, or even to £1,400, while the yearly writing off of capital, interest, etc., would be increased proportionately, each requirement now having to bear the full charge of its special machine. The effect on the working costs of the writing off of so large a capital expenditure incurred by unipurpose machines is very material; for example, the capital charges for a tractor costing £350 suitable for plowing alone, and allowing seven years' life and 100 acres per year, would be 10s. per acre, for 200 acres 5s. per acre, and even if an allowance is made for performance of light land work, subsequent to plowing, the cost would probably amount to 3s., equivalent to the cost of fuel (at 3 gal. per acre), and as great as, if not greater than, the wages of two operators.

The financial consideration of the problem brings out the advantages of a multi-purpose machine, a power unit—if it could be designed—to meet the majority of calls of the farmer, instead of a special power implement for each purpose. Such a desirable combination should never be lost sight of in any general investigation of the fundamental factors of design.

There will always be farms so large or special conditions of such a nature as to allow of the purchase of special machines for each purpose with a commercial advantage; such cases, however, must be considered individually, and are not dealt with here. There is no doubt, however, that despite the questionable soundness from a commercial point of view, of the use of many special purpose units for the average farm, there still remains a strong body of opinion that the use of such power implements is the right thing, and only the showing of the future, when the farmer has purchased on these lines, will clearly demonstrate whether due consideration had been paid to the financial aspect of the problem.

It is essential to bear in mind the incidence of the various duties called for from the tractor; will they so fall as not to

*Paper presented to the Institute of Automobile Engineers—slightly condensed.

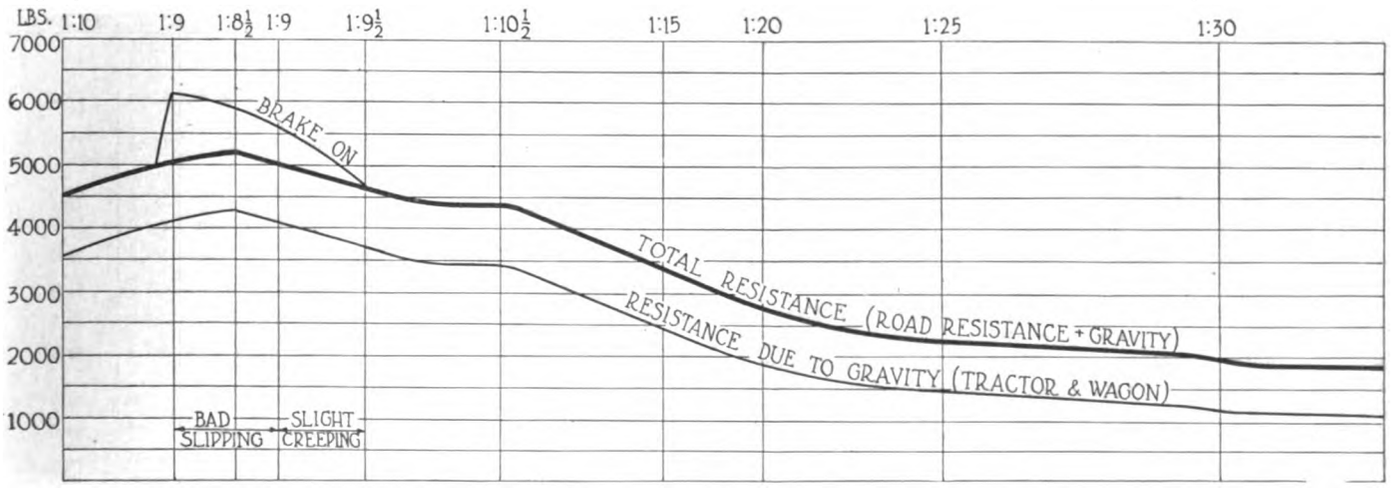

Fig. 1—Results of Road Resistance and Adhesion Tests (September 12, 1917)

Gross weight of tractor, 7.4 tons; gross weight of wagon, 8.7 tons; gross weight of complete train, 16.1 tons; weight on driving wheels (3 ft. 6 in. x 12 in.) 10,000 lb.; adhesion factor, without slip, 0.46. With slight creeping, 0.56, max., 0.62; road resistance per ton, av., 53 lb.; average speed, 1¾ m.p.h.; road surface, very good macadam, dry

Digitized by Google

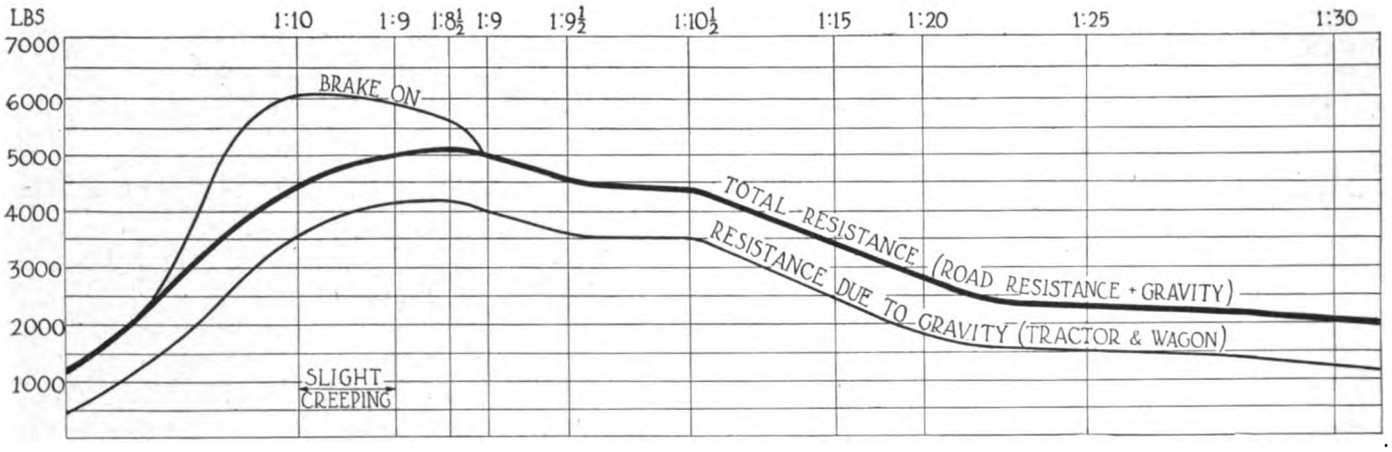

Fig. 2—Results of Road Resistance and Adhesion Tests (September 11, 1917)

Gross weight of tractor, 7.4 tons; gross weight of wagon, 8.7 tons; gross weight of complete train, 16.1 tons; weight on driving wheels (3 ft. 4 in. x 10 in.), 10,000 lb.; adhesion factor, without slip, 0.58; with slight creeping, 0.6; road resistance per ton, av., 53 lb.; average speed, 1½ m.p.h.; road surface, very good macadam, dry

conflict? That is to say, can the uses of such a power unit be reasonably well divided to cover the agricultural year with the help of horses which will be always available to a limited extent? It is held that they can, though each farmer must with his own conditions in front of him judge for himself. The requirements called for from a power unit during the agricultural year are:

(a) Plowing, dragging, rolling, drilling.
(b) Reaping, binding and leading.
(c) Threshing, pumping, pulping, chaff-cutting and grinding.
(d) Transport work to the station.

These duties are not likely to exceed 70 per cent of the total working days of the year.

It is not possible here to consider these operations in further detail, for we must confine our examination to the mechanical factors of the problem. The three principal uses which, by their requirements, govern the design of the tractor are:

(a) Road Work—Transport.
(b) Land Work—Plowing.
(c) Farmstead—Threshing, etc.

(a) governs the minimum axle loading, (b) governs the maximum axle loading, (c) governs the minimum power required.

Road Work

The basic factors governing the application of mechanical power for traction purposes are adhesion and resistance.

Tractive Adhesion.—The adhesion of the driving wheels on the road must be sufficient to utilize the power developed by the engine in overcoming the tractive resistance of the load and the tractor combined.

There exists a considerable amount of data relating to tractive resistance, but for tractive adhesion on common roads, little, if any, can be found. For traction on rails, the locomotive engineer has plenty of data obtained by the use of dynamometer cars, and from these have been developed recognized constants. The standard figure of adhesion is 0.25, *i.e.*, one quarter of the load on the driving axles can be used in drawbar-pull. It is stated that this figure rises to 0.35, but it is not advisable to use such a value in practice.

As no adhesion values were available for steel tires on common roads, experiments have been made to determine them. In these experiments a steam tractor was employed towing a loaded wagon by means of a recording dynamometer. In order to obtain maximum results the experiments were extended so as to traverse a steep hill, and even with this additional resistance it was still necessary to apply the brake to the wagon before the maximum value was exceeded, and slipping began.

It will be seen clearly that these experiments also afforded an opportunity of testing traction resistance constants, and this was done.

To make the results still more useful, the same tractor was fitted with rubber tired wheels and tested under similar conditions. The whole forms quite a useful combination of data for the designer of tractors for common roads, and the author is much indebted to Messrs. Ruston, Proctor & Co. for enabling the tests to be carried out. These results are shown in the Tables of experiments, Figs. 1 and 2.

From these it will be seen that the maximum value—*i.e.*, with slipping just beginning—is for steel tires 0.56, and for the rubber tires 0.6. It is suggested that in practice where country roads have to be taken into account, a safe value for steel tires would be 0.45, and for rubber tires 0.55, or if long life of tires is desired 0.5. This means, in effect, that in getting out the design of the tractor for road transport, which duty limits the minimum weight, the propulsive effort cannot be taken as exceeding 0.45 times the weight on the driving axle for steel tires. The high cost of rubber tires for road purposes with their special wheels seems hardly justifiable for the conditions obtaining on a farm.

Traction Resistance.—From the experiments, Figs. 1 and 2, the tractive resistance for a good macadam road comes out at just over 50 lb. per ton, the diameter of the hind wheels of the loaded wagon being 4 ft. by 9 in., that of the front 3 ft. 6 in. by 9 in., with steel tires. The values given in Table I are the results of experiments lately carried out over roads in California.

TABLE I—TYPICAL RESULTS FOR VARIOUS SURFACES

Test No.	Kind of Road	Condition of Road	Location	Traction Resistance	
				Total	Per Ton
29—30—31	Concrete (unsurfaced)	Smooth, excellent	Near Davis	83.0	27.6
*11—12	Concrete (unsurfaced)	Smooth, excellent	Near Davis	90.0	30.0
26—27—28	Concrete (⅜-in. surface asphaltic oil and screenings)	Smooth, excellent	Near Davis	147.6	49.2
13—14	Concrete (⅜-in. surface asphaltic oil and screenings)	Smooth, excellent	Near Davis	155.0	51.6
9—10	Macadam (water-bound)	Smooth, excellent	Near Davis	193.0	64.3
22—23	Topeka on concrete	Smooth, excellent	Near Davis	205.5	68.5
8	Gravel	Compact, good condition	Near Davis	225.0	75.0
†45—48	Oil macadam	Good, new	Near Sacramento	234.5	78.2
‡46—47	Oil macadam	Good, new	Near Sacramento	244.0	81.3
33	Gravel	Packed in good condition	Near Davis	247.0	82.3
18—19—20	Topeka on plank	Good condition, soft, wagon left marks	On Causeway near Davis	265.0	88.3
34	Earth road	Firm, 1½ in. fine loose dust	Near Davis	276.0	92.0
24—25	Topeka on plank	Good condition, but soft	Near Davis	278.0	92.6
1—2—3	Earth road	Dust ¾ to 2 in.	Near Davis	298.0	99.3
3—4	Earth	Mud, stiff, firm underneath	Near Davis	654.0	218.0
6—7	Gravel	Loose, not packed	Near Davis	789.0	263.0

*Graphic record indicates that the load was being accelerated when the test was started.
†Drawn with motor truck at 2½ miles per hour.
‡Drawn with motor truck at 5 miles per hour.

Digitized by Google

For the purposes of this investigation a value of 60 lb. per ton has been taken.

Having now the values for adhesion and resistance, it is necessary to inquire as to the load a farmer will require for road transport. As it is desirable that the tractor should work on the land with practically the same efficiency as a special purpose machine, heavy axle loading is prohibited, and it becomes necessary to proportion the tractor weight to fulfil this condition, and yet permit of the requisite adhesion for hauling the load on the road.

When the tractor is hauling a wagon in ordinary service the load may be adjusted to any condition or gradient. Is there, however, any other governing condition in which this adjustment cannot be made? A load that is in one, so to speak—and here a full-sized 4 ft. 6 in. threshing machine may be taken as a guide—such a machine weighs 4¼ tons, as a safe maximum say 4½ tons.

The next consideration is the reasonable maximum gradient a tractor may be called upon to face. If a maximum gradient of 1 in 10, and a tractor weight of 50 cwt. is assumed, we have 224 + 60 = 284 lb. as the total resistance per ton. Then the total load of 4.5 tons plus 2½ tons equals 7 tons, or a total propulsive effort of 1988 lb., which gives us, with a 0.45 traction adhesion, a load of 4400 lb. on the driving-axle. Obviously with a tractor of a total weight of but 2½ tons (say 15 cwt. on the front axle and 35 cwt. on the back), this axle weight cannot well be provided. The increased loading on the axle due to the reaction of the drive, the values of which are shown in Fig. 3, provides however a means of meeting this difficulty. The alternative method is to adopt artificial loading on the axle. Resolving the drawbar-pull into engine power at 2 m.p.h., at 70 per cent gearing efficiency we got a brake horsepower of the engine of 15.2, and at 80 per cent efficiency the power would be 13.2 approximately.

For still heavier loads or steeper gradients a larger power is required, and it is desirable therefore that this be provided if not incompatible with the other factors.

Work on the Land

The governing factors of successful working on the land are not easily determined, and apart from the difficulty of carrying out experiments there are such intangible things as the varying opinion as to allowable pressure on the soil to be taken into account.

It may be said generally, however, that weight is a very important consideration, and must not exceed a certain maximum, while additional tractive effort in excess of that consistent with this weight must be obtained by other means, projections on the wheels, spuds, etc.

The pressure which worked land will bear without injurious effect upon the crops, varies of course according to the nature of the soil. From the mechanical point of view the limit of pressure is set by the necessity to prevent sinking into the ground, an occurrence which is seldom solely due to excessive weight.

What usually happens is that owing to inadequate gripping power the driving wheels rotate and act as milling cutters, scraping out the soil from beneath.

The relative values of weight and spud area are very difficult to allocate so as to be able to make comparisons: for instance, a machine with a 30 cwt. axle loading and short spuds pulls partly by adhesion and partly by grip, and the latter is rendered more effective by the weight of the wheel holding the ground down during this action. On the other hand, a lighter tractor with 15 cwt. axle loading must pull very largely by grip alone, and the effectiveness of the grip is modified and reduced by the lighter weight behind it, and the greater rolling resistance per ton set up by the spuds.

Hence it will be seen that the data to be ascertained are the proper relation of pressure on the land, the pressure against it, and the action of the rim projection, strake, spud or grouser.

We have thus three prime conditions to be met for the majority of cases—

(a) Driving axle loading,
(b) Pressure against grips or spuds,
(c) Effect of rolling resistance.

Considering first pressures that have been usual on land work, we have:

Man's Shoes	8½	lb. per sq. inch
Horse's Hoofs	20	" " "
Cart Tires—		
Load 2 tons	40	" " "
Oil Tractor in use—		
3 tons on axle	25	" " "
with extension	16	" " "
Steam Tractor—		
3½ tons on axle	17	" " "

Assuming from our previous figure a static axle loading of 3920 lb., then with the driving wheels of the tractor 48 in. diameter by 12 in. wide, we get with a contact area of 288 sq. in. (sinkage of wheel ¾) a pressure per square inch of 13.6 lb.

The second part of the problem is more difficult, owing to the absence of data, but concluding that the strength of the ground is represented by its resistance to ploughing, Fig. 4 is useful.

Considering first pulling by grip alone (light tractors in Fig. 5) the suggested allowable pressures against a spud are given, and for average land 50 to 75 lb. per square inch may be taken as corresponding to approximately a plough resistance of 9 lb. per square inch. If it is assumed that the drawbar-pull is 2000 lb., and the loading 50 lb. per square inch, the pull if taken by one spud in each wheel would be 1000 lb., so that for a 12 in. wide wheel the spud would be 1.67 in. long for average land.

For light lands when the strength of the soil is low, with the same drawbar-pull, this depth would have to be increased about four times, *i.e.*, the spud would be 6.7 in. based upon the relative resistance given in the above table. This cannot be considered as a proposition to be recommended, owing to the necessarily greatly increased rolling resistance of the tractor, and a special device becomes necessary, such as an

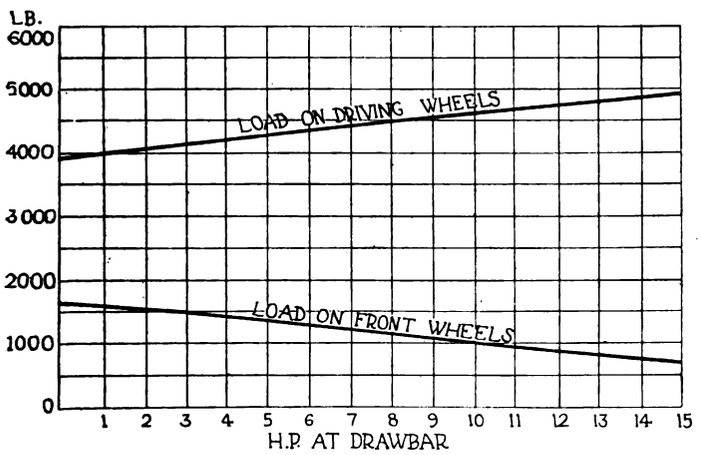

Fig. 3—Displacement of wheel loads due to turning moment and drawbar pull

Weight of tractor in working order, 2½ tons; wheelbase, 6 ft.; diameter of driving wheels, 4 ft.; height of drawbar from ground, 1 ft. 8 in.; power lost in rolling resistance taken as 20 per cent

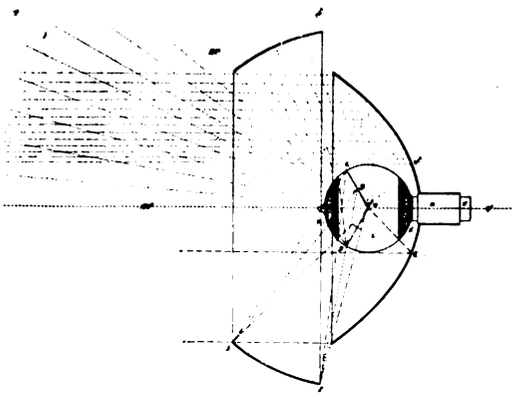
actuated spade, Fig. 6, fitted to the driving wheels, if efficiency is to be obtained. The mechanical complication and disadvantages of this method, even though they may be surmountable, are self-evident.



There is no doubt that many useful experiments can be carried out to determine the most efficient form of grip for varying conditions of soil and weight of tractor. On very soft land the wheeled tractor, either by reason of weight or spud pressure, is not suitable, and one of the track-laying type becomes essential. This, however, cannot be said to be at all necessary for the majority of English agricultural conditions.

(To be continued)

Some New Ideas Concerning Glare

THE subject of glare is still a mysterious one to many persons. The same as dirt has been defined as matter in the wrong place, so glare may be defined as light misdirected. When driving in an automobile at night we want plenty of light, but this light should fall on the road and not strike the eyes of pedestrians on the sidewalk or drivers of oncoming vehicles. Before the so-called glare can be eliminated it is necessary to locate the exact source of the rays that strike the driver and pedestrians.

Objectionable glare originates not only in powerful headlights, but also in the now so popular spotlights. Mr. Roffy of the Cellbeam Mfg. Co., Brooklyn, N. Y., who is probably one of the best authorities on this subject, having originated a number of headlamps and spotlamps now on the market, has a new theory regarding the cause of glare. He claims that it is entirely possible to produce a powerful projector

of compact dimension, and that the general glare emitted from bulb filaments can be reduced to a minimum by converting it into diffusive illumination.

This idea has been embodied in the Cellbeam projector recently placed on the market by the above mentioned firm. A spherical reflector corrected for aberation embraces the light source to a plane angle of 105 deg., and beyond the aperture of this main reflector there is an annulus of another reversed reflector whose focus is offset with respect to the focus of the main reflector. The result is that the light falling on this annulus is reflected onto the translucent frontal screen. The latter, receiving light from both front and rear, becomes a highly luminous surface, a surface of diffused illumination.

Italian Motor Car Industry

ITALY, in striking contrast to other European nations, has enormously increased her exports of motor lorries and cars during the last 3 years. This is shown by statistics issued by the Italian Ministry of Finance for the first five months of of 1917 (ended May 31), compared with the corresponding months of 1915 and 1916. During the first five months of 1915 Italy exported 2541 motor vehicles of all kinds. For the corresponding period of the present year the figures have been increased to 3647 automobiles.

The FORUM

Use of Heavy Fuels

By Charles E. Duryea

YOUR most pertinent remarks on heavy fuels in the issue of Dec. 6 call attention to some defects of our present construction. Using thermostats and getting as nearly to hot engines and heated mixtures as we may is, of course, along the right line, but why do we not cut the Gordian knot by going to air cooling, which uses much hotter cylinders and gets much greater economy with less complexity? The hotter cylinders not only use more of the heat produced but they have far less need for mixture heaters, for any heavy fuel deposited on an air-cooled cylinder wall finds that wall hot enough to vaporize the fuel and allow it to be burned as it should be.

I would disagree with your opinion that the change from gasoline to crude or heavier fuels will be a gradual development. On the contrary, it will be a sudden jump, brought about by the abandonment of one method and the adoption of something so totally different that there is no common middle ground. We have to-day a number of stationary and boat engines operating on kerosene which use very high pressures and show great economy. They ignite by pressure and so never miss an ignition. Surely, they have a big future. Is any one adapting them to auto work? If not, can any of your readers tell us why not?

Why do we not use coal gas made from coal as needed? Coal yields about two-thirds as much power per pound as a liquid fuel, but in a small producer we should allow some waste, say 25 per cent, which would make a pound of coal half as efficient, but since it only costs one-tenth as much it should yield five times as much power for a given cost. Is any one developing along this line? I am looking for the capital that is willing to help.

That "the thermal efficiency is such a miserable figure" is also too true. Higher compressions as mentioned above, constant compressions as in two-cycle, air cooling, leaner mixtures and similar remedies are all waiting to be further applied to the auto. When will we get them?

Hot Spot Must Be Studied

By R. J. Broege

Chief Engineer Buda Motor Co.

THE importance of the hot spot manifold cannot be emphasized too much and worked out to as near perfection as possible any too soon as to the location and amount of heat required. In fact, it is the writer's opinion that this will be very apparent this winter in the older type of engines, which have no arrangement for applying the heat to the carbureter or gas intake manifold to help vaporize the present-day fuel, which is getting heavier right along.

It is the writer's opinion that the temperatures of the gas mixtures at the moment of entering the cylinder are considerably lower than the general opinion among engineers and are governed by the amount of vacuum caused by the intaking of the gases.

The writer has not yet checked the exact temperature at the moment of the inlet, but past experience with the combination of the exhaust and intake manifold has led the writer to the belief stated above. We have made up a combination exhaust and intake manifold, the intake being entirely exhaust jacketed with the exhaust gases flowing directly around it and out through the manifold to the muffler. In the first place, this combination of gas intake and exhaust manifold led the writer to believe that this intake manifold would receive too much heat from the exhaust gases, but upon tests we find that there does not seem to be any appreciable difference between using 68 gasoline or straight kerosene. In fact, the horsepower showed in favor of the kerosene with either using additional hot air or without any additional hot air. The horsepower curves seemed to drop off 6 lb. on a 21-in. arm when using the hot air, whereas the maximum power obtained by the same engine is less than 10 per cent off the power obtained from a similar sized engine with a cold intake manifold or when entirely water jacketed.

The writer has had no chance to have a cold manifold made up so as to get the extreme conditions between the cold manifold and an exceptionally hot manifold with the entirely cold manifold or one entirely exhaust jacketed. As soon as we have these manifolds we contemplate conducting further experiments.

The Roadtractor

By George T. Strite

FOR years the farmer has been using his farm tractor when he has one for hauling large quantities of grain and other farm produce to the railroad station. For years he has been trying to use the same farm tractor to build new roads and keep up the roads. The farm tractor was designed and built for farm work on generally soft fields and farm lands. Some of the larger tractors have been fairly successful for building new roads and heavy grading.

There should be a machine designed and built especially for this work. I see no reason why such a machine should not be successful for both road building or at least keeping up good roads and also be with possibly some slight changes satisfactory for farm transportation work.

The farm tractor is designed to trail or carry all its load behind itself at a speed of 2 to 2 1/3 m.p.h. The present tractor is generally equipped with two speeds and sometimes three in which there is a low speed about 1½ to 2 m.p.h. and a high speed of 3 to 4 m.p.h. The two-speed tractor always has the plowing speed, generally plowing and high speed; and sometimes plowing speed and low speed. The plowing speed is used 85 per cent of the time. The low is used on hills and hard strips of plowing, generally gumbo streaks, which pull very hard.

The farm wagon seems to be the most practical vehicle for carrying most of the farm produce. The farm wagon will trail and carry heavy loads behind a tractor on plowing speed loaded, and on high when empty. On fairly good roads the farm wagon loaded will stand a speed of about 2¾ to 3¼ m.p.h. On rough roads 2 to 2 1/3 m.p.h. Empty they will stand a speed of 4 to 5 m.p.h. on good roads and 3 m.p.h. on bad roads. The road drag can run at 2¾ to 3¼ m.p.h., but this is generally too fast in my experience for the light road grader, which should travel at a speed of about 2 to 2 1/3 m.p.h.

It would seem the proper speeds for the roadtractor would be low about 2¼ m.p.h. If there is any direct speed it should be intermediate speed, as 60 to 70 per cent of the work will be done on this speed.

The farm tractor or truck will not be a satisfactory roadtractor for the following reasons:

First: The farm tractor is too slow and even if geared up is not built to stand road work or hard road travel.

Second: It is not sufficiently spring mounted or flexible enough for road work.

Third: The wheels on the farm tractor will not stand the constant vibration of road travel on road work. For farm work and pulling a heavy load on soft ground the wheels must be much larger and wider than necessary for road work or travel.

Fourth: The driver on the farm tractor is in the wrong place for road work.

Digitized by Google

Fifth: For either farm transportation or road making the truck is too fast and not capable of sufficient trailing capacity.

Sixth: For either farm transportation or road making the farm tractor lacks durability for the work, as it was not designed or built for this work and it is not speeded right for this work.

The successful roadtractor can never be a practical farm tractor and the successful farm tractor will never be a practical roadtractor.

The roadtractor must be capable of trailing.

It must be capable of trailing from two to five loaded wagons with 50 to 80 bu. of grain each or 1½ to 2½ tons per wagon. Also it should be capable of a small load on the roadtractor at a much slower travel than the ordinary truck and faster than the regular farm tractor.

Roadtractor Three Speeds

It must have three speeds. It must be designed to run on intermediate gear 85 per cent of the time when pulling or trailing loaded wagons. The low gear must be used for rough and bad portions of the road and climbing hills, the high speed only for returning to the farm empty. I have known of many of the farm tractors, especially the single-speed tractors, to be simply wrecked by the driver being in a hurry to get home and run the motor at a terrific speed going home empty and cause more damage to his motor and tractor than the field work.

Pneumatic Tires Necessary

The roadtractor must have rubber or pneumatic tired wheels and at the same time be so made that lugs or grounders can be put on. It would seem to me that a spring suspension could be used between the hub and the rim of the wheels. The automobile or truck would be simply impossible without the rubber or pneumatic suspension between the ground and the hub of wheel.

On the roadtractor the gears must be entirely inclosed, *final drive included.* The breaks must be many times as effective as the breaks used on the farm tractor.

The wheels could be smaller than used on the farm tractor and not so wide and larger than used on trucks. The wide wheel is a bad feature on hard roads. The wider the wheel on a farm tractor, the quicker it will go to pieces, especially on graded roads. It must also be kept in mind that if the wheels are too small and too narrow and there are only two drive wheels, then there will be trouble on soft and sandy roads where grounders must be used to increase drawbar pull to trail heavy loads.

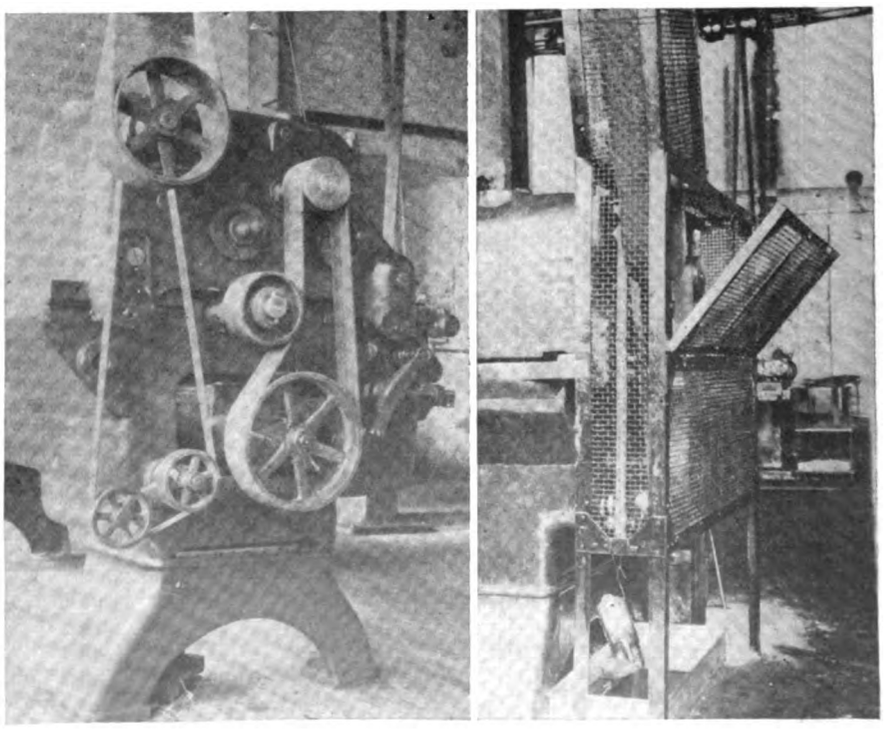
On the roadtractor the driver's seat should be in front, as the entire attention of the driver should be on the road ahead, which is not the case with the farm tractor, as the farm tractor operator must see and control the plows and other implements behind him.

The roadtractor should be so arranged so a service or belt pulley could be quickly put on. There are times when the farm tractor is busy in the field and belt work should be done at the same time, thus promoting efficiency.

The roadtractor should be equipped with electric starter and must be equipped with electric lights or some kind of lights.

The crawler or creeper type has great advantages over the wheel type on sandy or soft muddy roads, but again it has many disadvantages on good or even ordinary roads. In the first place, I doubt if a road speed of more than 3 or 3½ m.p.h. would be practical for this type of machine. The upkeep of the tracks and parts of tracks would be great as compared with the wheel type. A satisfactory spring suspension suitable for road work would be almost out of question.

The four-wheel-drive roadtractor would be very desirable if the cost and the price it would have to sell for would not be prohibitive. The wheels could then be much smaller and narrower and still have the traction to pull the desired load.



It has often occurred to me that the two rear wheels with axle and differential complete could be slipped out from under the ordinary 2½ to 3-ton truck and a set of tractor wheels with the axle and differential and proper reduction gears slipped in and coupled up to the regular standard drive shaft from transmission of the truck. This would make a three-speed outfit and this could be made to be a very satisfactory trailing outfit for road work and could also be used for pulling two plows or less in farm work in emergency.—GEORGE T. STRITE, *Tractor Engineer*, New York City.

Points in Design from a Driver-Engineer

By G. W. Bolus

THE motor base should be so designed as to permit the average driver renewing the oil in the crank base, or sump without making it necessary to drop the pan, crawl under the car and remove the drain plugs. A reasonably fool-proof valve could be arranged whereby the oil could be quickly drained from the crankcase by simply removing the motor hood. As we all know, crankcase dilution is becoming more and more of a factor in the operation of a motor car in cold weather, which makes it necessary to remove the oil more frequently, and unless the operation is made very simple, this point is very apt to be neglected or put off, to the detriment of the bearings of the motor.

I have noticed, from time to time, in the journals, comments on the slanting windshield and the hand accelerator. I submit that the slanting windshield is an advantage, not only in reducing wind resistance, but in that it entirely eliminates blinding of the driver from the headlights of a car in the rear being reflected against the windshield and into his eyes. On the hand versus foot throttle or accelerator, I think they are both necessary. We have decided use for the hand throttle when starting a car on a severe grade, as it is necessary to use one foot for the clutch and the other foot for the service brake, so here the hand throttle comes in very handy in bringing up the speed of the motor to a point where it will pick up the load.

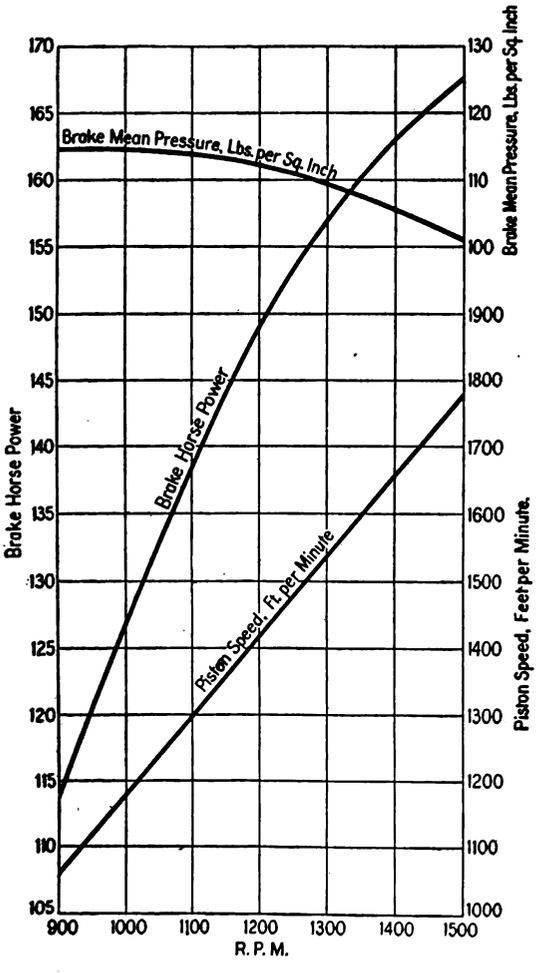
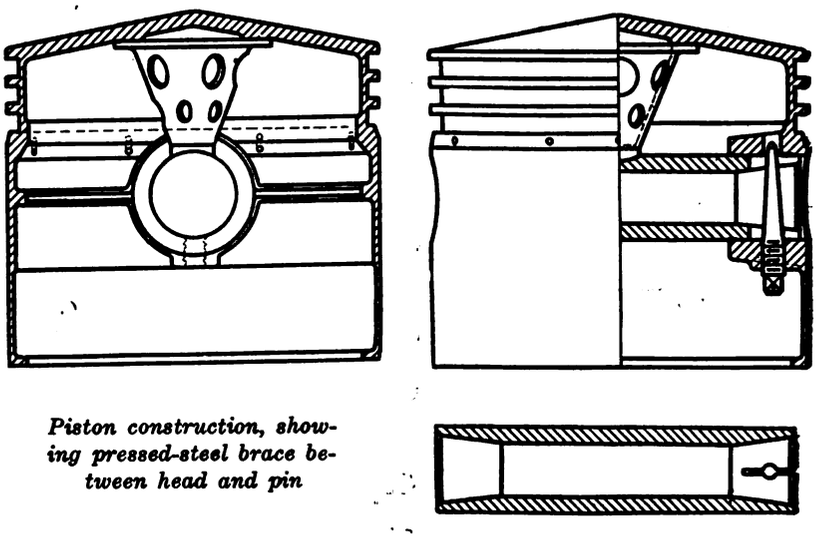
The 160-Hp. Benz Aircraft Engine

Design and Performance Data of One of Germany's Leading Aircraft Engines—Has Longer Stroke and Is Somewhat Lighter Than the Mercedes



IN previous issues we have given detailed descriptions of the Mercedes 160 and 260 aircraft engines, and we are now in position to furnish rather complete data of the Benz 160-hp. engine. The data and drawings are reproduced from *The Automobile Engineer*, which published them with the permission of the British naval and military authorities.

Table I



Number and arrangement of cylinders	Six, vertical
Bore, in.	5.12
Bore, min.	130.0
Stroke, in.	7.09
Stroke, min.	180.0
Stroke/bore ratio,	1.385 :1
Area of one piston, sq. in.	20.60
Total piston area of engine, sq. in.	123.60
Swept volume of one cylinder, cu. in.	146.05
Total swept volume of engine, cu. in.	876.30
Volume of clearance space, cu. in.	41.65
Compression ratio. Total volume/clearance volume.	4.50 :1
Normal b.h.p., b.h.p.	160
Normal speed, r.p.m.	1,400
Piston speed, ft. per min.	1,655
Brake mean pressure, lb. per sq. in.	103.00
Mechanical efficiency (calculated), per cent.	87.50
Indicated mean pressure (calculated), lb. per sq. in.	117.7
Fuel consumption per b.h.p. hour (s.g. 0.730), lb.	0.520
Brake thermal efficiency (18,600 B.t.u.'s/lb.), per cent.	26.32
Indicated thermal efficiency, per cent.	30.10
Air standard efficiency, per cent.	45.20
Relative efficiency, per cent.	66.60
Cu. in. of swept volume per b.h.p., cu. in.	5.48
Sq. in. of piston area per b.h.p., sq. in.	0.773
Hp. per cu. ft. of stroke volume, hp.	315.5
Hp. per sq. ft. of piston area, hp.	186.4
Direction of rotation of crank and propeller	Anticlock
Normal speed of propeller, r.p.m.	1,400
Oil consumption per hour (specific gravity, 0.900), lb.	4.93
Oil consumption per b.h.p. hour, lb	0.031
Number of carbureters	Two
Type of carbureters	Benz
Fuel consumption per hour (specific gravity, 0.730), lb.	83.2
Number and type of magnetos	Two ZH6 Bosch
Firing sequence of engine	1, 5, 3, 6, 2, 4
Ignition timing (degrees early, full advance)	32
Inlet valve opens	Top dead center
Inlet valve closes	60 deg. late
Exhaust valve opens	60 deg. early
Exhaust valve closes	18 deg. late

Digitized by Google

Above—Tubular connecting-rod with central oil lead for piston pin; also cylinder unit. On left, induction system; on right, section through crankcase; below, valve mechanism

A characteristic feature of the Benz engine is the long through bolts by means of which the two halves of the crank chamber are held together. The length of these through bolts varies, those at the middle of the engine being longest and those at the ends shortest, owing to the slope of the crankcase bottom. The crankshaft is supported between the two halves. Apparently these through bolts also serve as cylinder holding down bolts, though this cannot be seen from the drawings. There are, of course, a good many additional holding down bolts

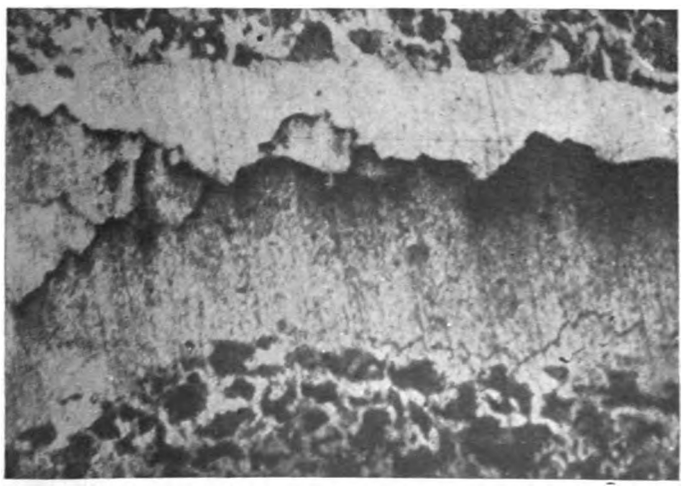
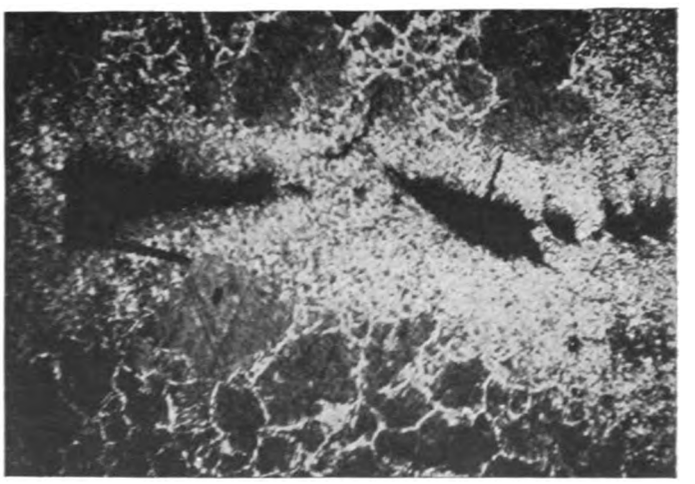
Hurried Processes Developing Faults

Microphotographs, When Analyzed, Indicate Lack of Care in Inspection Department—Some Defects May Be Traced Back to the Billet—Others Originate in the Forge

By J. Edward Schipper

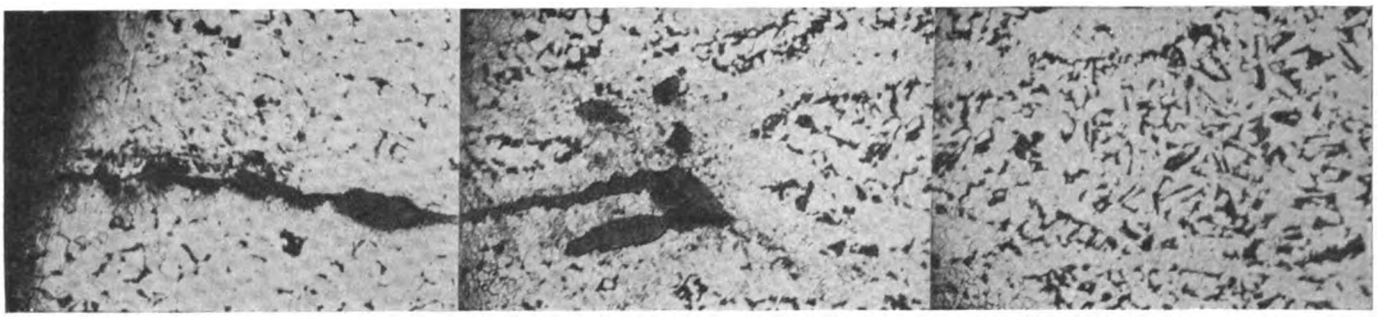




Figs. 1 and 2—Quenching crack which started from a surface crack. Probably due to shearing too closely. Nickel chrome steel, 0.40-0.50 carbon gear blank

MANUFACTURERS have lately noticed a tendency toward increased defectiveness in materials. Throughout the country there has been a general speeding up in the output of all kinds of products, and sometimes this has been accompanied by a decline in quality. This is a most serious matter where the material affected is used in the manufacture of vital parts.

Defects have been found in open-hearth high and low carbon steels, as well as in some of the highest grades of alloy steels. Some of these can be traced directly to the billet, while others, especially defects in gear blanks, originated in the forge. These defects, which were practically unknown when materials were not in such strong demand as they are now, are all evidences of haste, and sometimes the old proverb that "Haste makes waste" is borne out to a marked degree in that expensive parts and operations are wasted because of hurried handling during the early stages of manufacture.



The above statements are not based on conjecture but are amply borne out by researches in the laboratory. The microphotographs shown herewith indicate defective material caused by faulty handling at different stages. Figs. 1 and 2 show a continuous crack in a gear blank of nickel chrome 0.40-0.50 carbon, heat-treated steel. We have here a case where a small crack in the surface was enlarged during heat-treating. This is what is known as a quenching crack, which started from a very small surface defect, probably caused from shearing too close under heat treatment. The line of weakness developed so that the continuous crack finally resulted. The original microphotograph is magnified 240 diameters, and the reproduction herewith reduces this to 100 diameters. The breaking area on the outside shows the edge of the blank with the crack extending inward, as indicated. Careful work in the inspection department would have caught the surface crack in the blank, and if this had been

Digitized by Google

Figs. 5, 6 and 7—Seam in a 0.15-0.25 carbon steel gear blank which could have been avoided by proper inspection and chipping while in billet before rolling into bar form

chipped out the deep break illustrated would have been eliminated, or, rather, would never have been started. This is a defect of workmanship rather than of material.

A good illustration of faulty material is given in Fig. 3. The decarbonized area is clearly shown. This is a 0.35-0.45 carbon steel connecting-rod, and the trouble is probably due to insufficient cropping or to bad mixing in the first place. The cropping percentage has been reduced from 25 per cent to 15 per cent in some instances, and naturally this gives rise to an increased percentage of defective material. It is a much more difficult thing for the metallurgist to discover every defect than it is for the steel manufacturer to stop them. This shows what the parts and car companies have to contend with in order to secure good materials under present conditions.

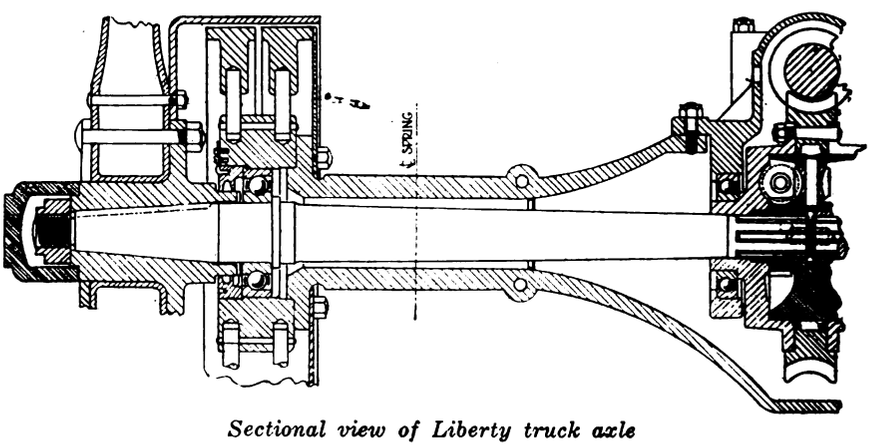
Another example of bad material is given in Fig. 4, where a distinct pipe is shown. The material from which this was taken is 0.37-0.47 carbon steel crankshaft stock. The magnification is 240 diameters on the original micrograph. The line of weakness with the clearly defined pipe can readily be seen on the micro.

Figs. 5, 6 and 7 illustrate a seam in a low-carbon gear blank. The carbon content is 0.15-0.25 per cent, the three micros going together in the order named. The defect in the billet has been increased by rolling into bar form, and the result is the seam, which is clearly shown in the micro. The seam has been rolled back on itself, as shown in Fig. 6, where the break area of the seam is doubled over into U form.

This could be avoided by proper inspection of the billets. If the billets were properly inspected and chipped before rolling into bars, this would eliminate the possibility of a small crack in the billet being extended into a seam in the bar. Manufacturers are avoiding difficulties of this kind by carefully supervising the workmanship and materials which they are securing. Conditions have now arisen where greater care than ever must be used in this respect, not only that the best possible product may be obtained, but also to reduce losses resulting from having to scrap material which besides being expensive in itself may have had considerable machine work expended upon it.

Liberty Worm-Driven Truck Axles

Made in Four Sizes for Trucks Up to 5 Tons Capacity—Semi-Floating Type and Fitted with M. & S. Differential

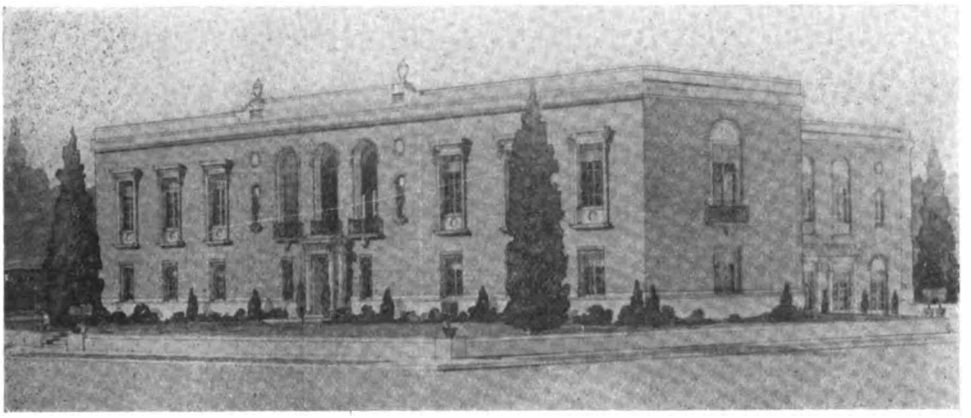


AN announcement has just been made regarding the product of the recently organized Wagner Axle Co., Anderson, Ind.—the Liberty axle. This axle is to be made in four sizes, adapted for use on trucks of 1½, 2, 3½ and 5 tons respectively. No radical features are embodied in the design, which is rather along conservative lines, incorporating only well-tried ideas. It is a worm gear axle of the semi-floating type, equipped with the M. & S. differential. The latter is of the type which makes it impossible for one drive wheel to spin, and a considerable saving in tires, as well as elimination of shaft breakage, is expected from this feature. The worm is of 3½ per cent nickel steel, the gear of special phosphor bronze and the differential case of cast steel. The differential gears rotate in an oil bath, insuring perfect lubrication.

An interesting feature is the worm carrier—a solid steel casting containing the worm gear and differential. This casting is provided with two ears so that, upon the removal of eight bolts, it can be taken out of the axle housing and any adjustment easily made.

Another feature which is thought to be a distinct advance in axle construction is the system of brakes. These brakes are of dual internal double expansion type and provide ample braking surface. They were designed for the Liberty axle.

The axle shafts are made of chrome-vanadium steel and heat-treated. They are of large proportions and built to withstand the most severe usage. The bearings are of the ball type, self-aligning and capable of sustaining end thrust.



The Wagner Axle Co. was organized some time ago with a capital of $2,000,000 and has a plant at Anderson, Ind.

Dayton Engineers' Club to Dedicate Newly Built Home

New club house of the Engineers Club of Dayton

AS one of the great centers of industry of the country Dayton has its engineers club, a place where men connected with the manufacturing industries in a technical capacity may meet socially. It is a live organization, having at its head a number of men of national prominence, and the automotive industries are well represented in the membership. The president of the club, Col. E. A. Deeds, is chief of the Aircraft Production Board, and is devoting his entire time to the war program. Among the vice-presidents are C. F. Kettering, the new president of the S. A. E., and Orville Wright, co-inventor of the airplane.

The membership having grown to about 300, the club felt the need for a new home. Plans were drawn up for a modern clubhouse, and the structure has been completed and will be dedicated on Saturday afternoon and evening, Feb. 2, with fitting ceremonies. Following are some of features of the clubhouse, which is conveniently located at the southeast corner of Monument Avenue and Jefferson Street facing the river. In the design of the building classical lines have been followed. It is three stories high, facing 150 ft. on Monument Avenue and 125 ft. on Jefferson Street.

The exterior is built of Bedford, Ind., limestone, and soft-toned gray buff brick laid in Flemish pattern with wide white mortar joints. The design is a strong Georgian effect giving a dignity and refinement well adapted for an engineering building.

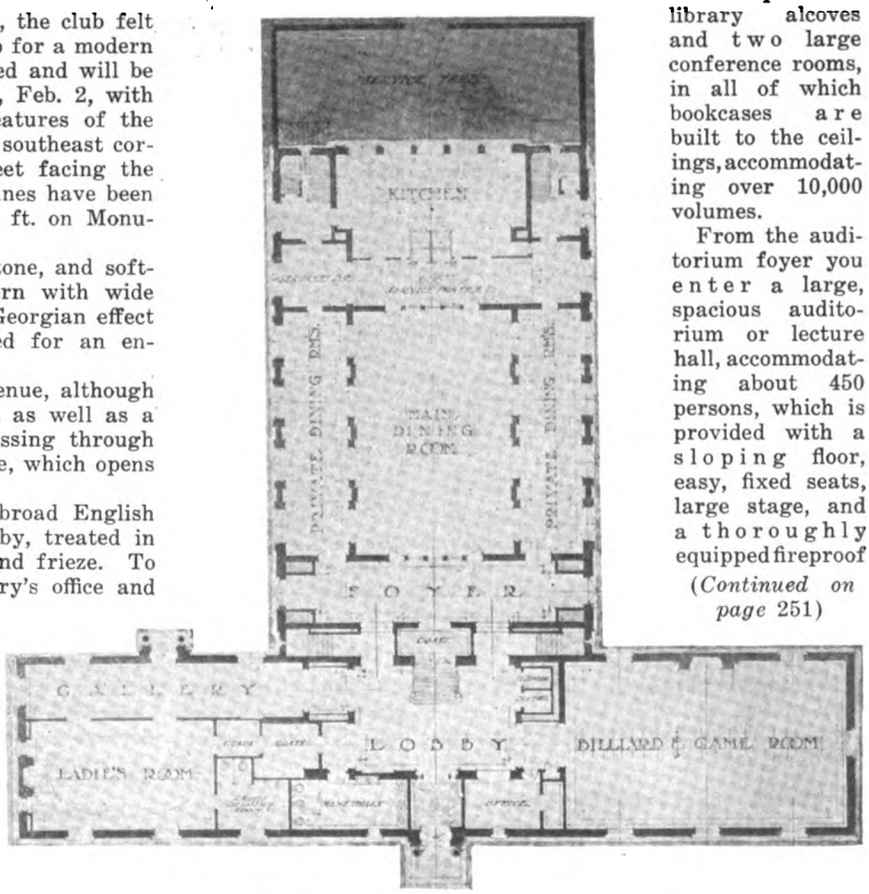
The main entrance fronts on Monument Avenue, although there is also an entrance on Jefferson Street as well as a porte cochere entrance on the east side. Passing through the main entrance one enters a simple vestibule, which opens into a very attractive first floor lobby.

Directly south of the lobby entrance is a broad English stair leading to the spacious second floor lobby, treated in Caen stone effects, with ornamented ceiling and frieze. To the right on entering are located the secretary's office and telephone booths, and beyond is a large billiard and game room, which is provided with a large stone fireplace, English ceiling and wainscoting and cork floor.

To the left of the lobby is a broad visiting gallery at the east end of which is the porte cochere entrance. Entrances from the gallery also open to the sunken garden to the south and the large ladies' reception room carried out in the Adam period. A ladies' retiring or dressing room adjoins the reception room, while check and toilet rooms are conveniently located.

South of the lobby and down fine marble steps is the dining-room foyer, with checking facilities, and entrance to the sunken garden to the east and Jefferson Street to the west.

Directly south of this foyer is the main dining-room, off which open eight private dining-rooms, all of which may be thrown together with the main room, making a large room for banquet purposes. South of the dining-room is a spotless white serving-room and kitchen, provided with the latest improved equipment for efficiently handling the service of the club.



From the second floor lobby above referred to open a large loggia to the north, large lounging room to the west, library and conference rooms to the east, and an auditorium foyer to the south.

The lounging room, located directly over the billiard room, is 30 x 50 ft., with a large stone fireplace on the south side, high English wainscoting and heavy wood beamed ceiling, all kept in soft quiet coloring, making a restful atmosphere.

Just east of the lobby is located a large library and reading room, off which open two library alcoves and two large conference rooms, in all of which bookcases are built to the ceilings, accommodating over 10,000 volumes.

From the auditorium foyer you enter a large, spacious auditorium or lecture hall, accommodating about 450 persons, which is provided with a sloping floor, easy, fixed seats, large stage, and a thoroughly equipped fireproof

Fuel for Automotive Apparatus*

Straight Refinery Gasoline, Cracking Process Products and Blended Fuels — Distillation Curves of the Different Fuels and Their Adaptability to Present Day Engines—Production Figures

By Dr. E. W. Dean
Petroleum Division, U. S. Bureau of Mines

THE present paper deals with certain mutual problems of the two industries of automotive engineering and petroleum refining. A brief preliminary discussion seems to be in order to explain why a chemist is elected to present information apparently not related to his normal field of work.

The Bureau of Mines has for several years been conducting scientific investigations in the field of petroleum technology. This work was begun through the establishment of a chemical laboratory for the testing of oils. It was, however, recognized at an early date that little of practical importance could be accomplished if activities were limited to such a narrow scope. When the present petroleum division of the Bureau was organized the chemical section of this division was made to include with its laboratory investigations studies in the fields of petroleum refining and utilization.

The Bureau was early impressed with the general failure of producers and users of petroleum products to work together in dealing with the many problems that are of mutual interest. It is now thought that no more important end can be accomplished than to interest refiners and automotive engineers in the advantages of co-operation.

The principal petroleum products in which automotive engineers are interested are gasoline and lubricating oil. At present the latter does not seem to demand as much attention as the former, and although there is little doubt as to the advantages to automotive engineers of a knowledge of the manufacture and properties of lubricants, it seems most desirable at present to concentrate efforts on the obtaining of a solution of the fuel problem.

Gasoline Problem of Chief Interest

During the past few years the demand for gasoline has increased far more rapidly than the supply of raw material from which it is produced. Consequently there has been a general change in refinery practice with the production of so-called heavy gasolines, which are actually of relatively low average volatility. Although this change in quality is not necessarily deterioration, it has brought to the attention of designers and users of internal combustion engines problems that did not exist in the past. Coincident with the change in quality there has been an increase in market price and a threatened condition of shortage in supply, so that the automotive engineering industry now has for solution the complex problem of devising equipment for the utilization of fuel of low volatility and at the same time getting a greater production of effective power from the quantity of gasoline used.

Properties and Production of Gasoline

Before beginning the most important part of this paper—that which discusses the possibilities of increasing the supply of fuel and the efficiency of its utilization—it is desirable to consider briefly the characteristic qualities of gasoline and the possibility of variation among these as influenced by refining methods. It is already understood by automotive engineers that the name gasoline is decidedly indefinite in its meaning and that it includes a heterogeneous class of petroleum products that have in common only the power of enabling automobilists to start and operate their engines. The following discussion is intended to show some of the characteristic differences among types and grades of gasoline and to explain and perhaps justify the changes in quality that have occurred recently.

Review of Refinery Methods

There are now three general methods by which gasoline is obtained from raw material. The oldest and still the most important is the ordinary refinery process of distillation from crude petroleum. A second method, also used in refineries, is the pressure-cracking process, in which, instead of crude petroleum, heavy distillates, such as gas oil or fuel oil, are used as raw material. The third method involves the extraction of gasoline from natural gas, either by the absorption or the compression process. The product thus obtained is commonly called casinghead gasoline.

An adequate discussion of the details of any one of these processes is beyond the scope of the present paper, and it is therefore necessary to pass this interesting field with a brief word of mention. It may be stated, however, that the straight distillation method is highly developed and that improvements in it offer only moderate possibility of increasing the supply of fuel. Some gasoline and naphtha still goes into the kerosene fractions, but wastes of this sort are not important in the present situation. The cracking process is as yet only partly developed, and in the future its use will undoubtedly be considerably increased. It is not to be expected, however, that there will be more than gradual development in this field even if the Standard Oil Company should decide to license the Burton process for general use at an early date.

Other cracking processes are being installed on a commercial scale, but as yet seem to be limited to the small unit stage. The extraction of gasoline from natural gas is likewise a method that is growing in use, and it is difficult to predict just what can be expected from it on the basis of data now at hand. The recently developed absorption process makes it profitable to extract gasoline from gas not sufficiently rich to be treated by the compression process, but resources in this direction probably cannot be expected to develop in more than gradual fashion.

Properties of Straight Refinery Gasoline

The most familiar type of fuel, that produced from crude oil by the distillation method, is commonly described as "straight refinery" gasoline. This type of gasoline, as ordinarily refined, is colorless and possesses an odor varying from actual sweetness to the slightly disagreeable quality characteristic of kerosene. The hydrocarbons of straight

*Paper read at the S. A. E. winter meeting.

Digitized by Google

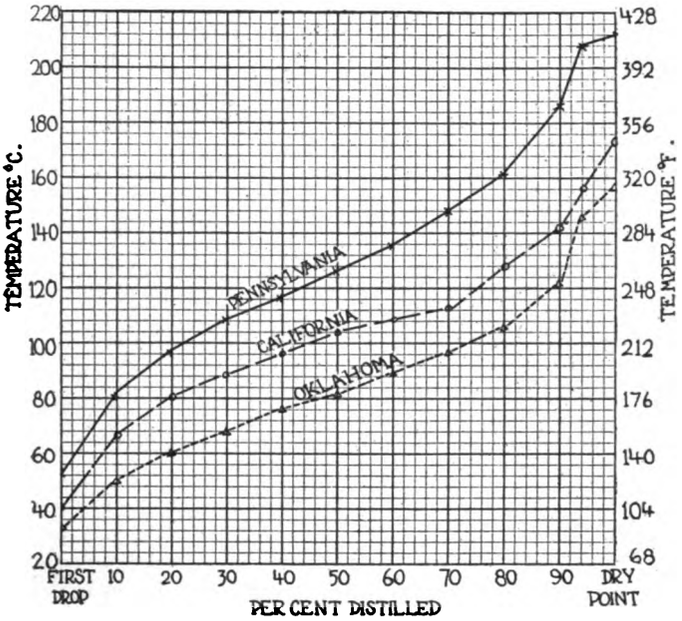

Fig. 1—Showing similarity in form of distillation curves of straight refinery gasolines of different degrees of volatility and from different parts of the country

refinery gasoline are of the so-called saturated class and are inactive when treated with such reagents as bromine, iodine and cold concentrated sulphuric acid. They are, however, slightly attacked by fuming sulphuric acid of moderate strength and by nitric-sulphuric acid mixture.

Straight refinery gasoline may vary within wide limits in the property of volatility, but the distillation curves obtained by plotting the results by the Engler test have a more or less characteristic form. Fig. 1 shows the distillation curves of three gasolines of various degrees of volatility obtained from different types of crude petroleum. The percentage marks are plotted as ordinates and temperatures as abscissas. The curves slope upward rather sharply from the initial boiling point to approximately the 20 per cent mark. From this point the graph proceeds as practically a straight line sloping gradually upward to about the 90 per cent mark. Here another steeper slope commences, which generally proceeds to about the 95 per cent mark, and then breaks sharply. This break is due to the fact that the dry point is not actually the 100 per cent mark.

Gasoline from Cracking Processes

The characteristic properties of cracked gasoline are odor and content of unsaturated or olefin hydrocarbons. Untreated cracked distillates have a particularly rank and unpleasant odor, which can, however, be practically eliminated by treatment with a small percentage of sulphuric acid. The odor of a well-refined cracked gasoline is not noticeably disagreeable, but has a definite quality and pungency that distinguishes it from gasoline of the straight refinery type. This odor is admitted to be somewhat undesirable, but is not a serious objection. The other characteristic property of cracked gasoline is a considerable content of unsaturated hydrocarbons, compounds that react with such chemicals as bromine, iodine or concentrated sulphuric acid.

The amount of material removable from the gasoline by treatment with an excess of cold concentrated sulphuric acid is generally called the percentage of unsaturation. The cracked gasolines usually marketed are acid refined and blended with straight run and casinghead products and generally do not contain over six per cent of hydrocarbons removable by sulphuric acid. The volatility curves of cracked gasolines are, like those of straight-run products, controlled by the method of refining, but the characteristic general form is the same as for the refinery distillates. Fig. 2 shows the distillation curve of an unblended cracked gasoline compared with that of a straight refinery product that happens to be of the same average volatility. The form of the two curves is almost identical.

Natural gas gasoline is of such a volatile nature that it is usually blended with a considerable proportion of heavier gasoline to reduce its vapor pressure so that it can be shipped and used safely. Its chemical and some of its physical properties are identical with those of the straight refinery type of product. It is colorless, of sweet odor, and inactive with sulphuric acid, bromine and iodine. The volatility of unblended casinghead gasoline is a property concerning which the Bureau has few data. This product is rarely used as such except perhaps in gasoline gas machines. It is usually marketed as a blend, either with a heavy naphtha produced by the ordinary refinery process or with straight refinery gasoline of high endpoint.

The term heavy naphtha is used to designate a distillate which does not contain the low boiling fractions included with ordinary gasoline. The blending of casinghead gasoline with the straight run product is generally done in refineries, many of which make a practice of buying all of the former they can obtain and adding it to the distillates produced from crude petroleum. The blending of casinghead gasoline with naphtha is generally done either by the companies that produce the former from natural gas or else by blending companies.

Desirable Properties of Gasoline

The desirable properties of gasoline and some laboratory tests and specifications for determining them have been discussed in a recent technical paper published by the Bureau of Mines. This paper was intended chiefly for the information of refineries and chemists but a brief review of some of the considerations mentioned may not be out of place here.

The requirements for a satisfactory fuel are as follows:

1—That it shall permit ready starting of a cold engine;

2—That it shall permit smooth and reliable operation of an engine at varied and rapidly changing loads and speeds;

3—That it shall not contain substances such as free acid which by corrosion or otherwise injure an engine;

4—That there shall be a minimum tendency for either solid or liquid residues to accumulate in the engine.

It is also desirable that gasoline shall not be of such nature as to be subject to excessive evaporation losses in storage or handling and that it shall not be too dangerous. These latter requirements are indefinite, however, and vary with climatic conditions. In addition they are likely to interfere with the starting qualities of gasoline if satisfied too thoroughly.

The second and third requirements are generally satisfied by present refinery practice. The Bureau has heard no complaints either of corrosive action due to free acid in gasoline or of lack of flexibility in engine operation. The first requirement, easy starting of cold engines, seems to be least generally met as the present tendency of refineries is to

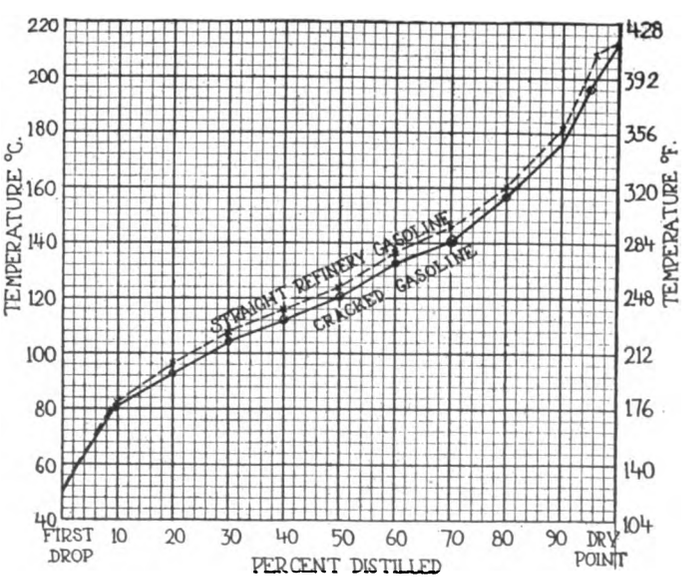

Fig. 2—Showing similarity in the distillation curves of cracked and straight refinery gasolines. Upper curve represents a straight refinery gasoline produced in Oklahoma—lower curve an unblended cracked gasoline produced by the Rittman process

Digitized by Google

market gasoline of relatively low average volatility. There seems to be little possibility of improvement in this quality and the problem of easy starting will undoubtedly have to be solved by engine designers.

The requirement that gasoline shall not leave a solid or liquid residue in the engine is one that frequently is not satisfied, according to reports from many makers and users of engines. Complaints are heard to the effect that there are sometimes gummy deposits in carbureters and manifolds, that excessive carbon deposits collect in cylinders, and that heavy fractions of gasoline are unburned and forced past cylinder rings into the crankcase oil. Difficulties are without question frequently due to improper engine adjustment and operation, but the gasoline is undoubtedly to blame in some cases. The accumulation of gummy deposits in carbureters and manifolds is a type of trouble for which there does not at present seem to be any definitely established explanation. The Bureau is at present studying this problem but has not yet enough information at hand to make it desirable to attempt an adequate discussion. Fortunately this type of engine trouble does not seem to be of frequent occurrence.

The two most important types of residue are carbon, which collects in the explosion chamber, and heavy fractions of the gasoline that condense and escape past the piston rings into the crankcase. Carbon deposition is frequently due to improper carbureter adjustment and can generally be minimized if a sufficiently lean mixture is used. Such deposition is, however, in common with crankcase oil pollution, often due to the use of gasoline containing too great a proportion of heavy ends, which in everyday language means kerosene. The term used by the refiner and oil chemist is "high endpoint" and means that when the gasoline is subjected to a distillation test the presence of high-boiling fractions is indicated. These fractions undoubtedly are not vaporized even in cases when no fuel troubles are experienced but are burned while in the form of a fine spray, in the same way that coal dust or grain dust burns explosively.

Fuel trouble due to high endpoint occurs when heavy constituents are present in excessive proportion; so that instead of holding up in spray form drops of considerable size precipitate. These settle on cylinder walls and piston heads and cause trouble in a variety of ways. Lubrication is interfered with, there is deposition of carbon through cracking and liquid residues may be forced past the piston rings and mixed with the lubricating oil. There may be other ways in which trouble is caused but those already mentioned are sufficient to indicate the disadvantage attendant upon the use of gasoline of too high endpoint in the average engine.

Unfortunately it is a difficult matter to set any kind of a definite limit that serves to indicate when the danger line in endpoint is passed. There are on record cases that seem to indicate that trouble has been caused by the use of gasoline of endpoint lower than 400 deg. Fahr. On the other hand a tremendous quantity of gasoline is being used, generally without more than imaginary fuel trouble which has an endpoint as high as 450 deg. In some cases 500 deg. endpoint gasolines are satisfactorily employed and the author is acquainted with one man who during the summer months regularly mixed with his gasoline a fourth of its volume of kerosene and obtained satisfactory results.

There is no question upon which it is easier to start an argument than on the proper endpoint of gasoline. The Bureau of Mines has up to date taken the stand that the only evidence it could depend on is the general marketing practice of refiners and on this basis it appears that the maximum satisfactory endpoint for a properly balanced gasoline is between the limits of 400 deg. and 450 deg. Fahr.

Objections to Blended and Cracked Products

There is still a tendency on the part of some users to consider that the only desirable variety of gasoline is a highly volatile product obtained by the straight refinery method. Blended casinghead gasolines are claimed to be dangerous, to deposit carbon and to stratify or change their composition in different parts of a storage system. Cracked gasolines are believed to be of vile odor and to polymerize in carbureters and manifolds and to leave excessive carbon deposits in cylinders. Straight refinery gasolines of high endpoint are likewise condemned on the ground that they are bad in starting an engine and that they deposit carbon and pollute the crankcase oil.

These beliefs are not without some foundation of fact. There is little doubt that from the point of view of the average user the most satisfactory fuel ever produced was a straight refinery gasoline testing 70-deg Baume or higher. This type of product was relatively dangerous in handling and was subject to high evaporation losses; but these disadvantages were ones to which users of the past were educated and which were considered characteristic of gasoline. The fact that gasoline was treated with proper respect minimized in a large degree the first disadvantage and its relatively low cost minimized the second. Gasoline of this type worked satisfactorily under almost any sort of engine conditions and in any event was rarely blamed for trouble. In earlier days the custom when anything went wrong was to swear at the engine rather than at the fuel.

When the newer types of gasoline were first introduced the trouble and dissatisfaction that immediately arose was not without some just cause. In many cases the process of blending casinghead gasoline was not properly conducted and in any event 70-deg. Baume gasolines of this type could not help being dangerously volatile. Methods of refining cracked gasoline were not perfected when these distillates were first marketed and they certainly did not compare favorably with straight run products in the matter of odor. It is likewise possible that there may actually have been cases of polymerization with troublesome deposition of gummy resinous material. When heavy straight refinery gasolines were first used engines were not designed or adjusted for their consumption and difficulties naturally arose. At present the methods employed in production and refining have been so improved that the bulk of the gasoline now on the market is really of excellent quality.

Cracked and Natural Gas Gasolines

Both cracked and natural gas gasolines are put out in the form of blends that the average user cannot distinguish from straight refinery products and which have actual elements of superiority over the latter as now marketed. Heavy gasoline is, of course, deficient in the property of easy starting, but this objection is balanced by the fact that it actually contains more heat units per gallon and permits the development of more power. There are certain other admitted objections to relatively non-volatile gasolines, but these are chiefly of the sort that can be obviated by proper engine design and adjustment. The Bureau has yet to receive proof that a gasoline of 400 deg. Fahr. drypoint and a properly balanced range of volatility (which means that from 15 to 20 per cent of constituents distil below the boiling point of water and that the other fractions are reasonably evenly distributed) has failed to yield satisfactory results in a well adjusted automobile engine of up-to-date design. In many cases gasolines of as high endpoint as 450 deg. Fahr. are being used with satisfaction.

The main advantage of the present type of fuel is that its introduction has permitted the producers to keep pace with the demands made upon them. If the older standards of quality had been maintained prices would have soared far above their present high level and in addition there would have been to-day an actual shortage. Few users of automobiles would prefer limitation in their supply of fuel to the slight inconvenience of having to treat their engines with the care and respect these complicated mechanisms actually deserve.

It is a difficult matter to make accurate predictions for the future of a situation involving as many variables as does the automotive fuel market. The Bureau of Mines is able to obtain reliable information concerning gasoline production and quality but realizes its inability to foresee all factors governing market conditions. It is therefore necessary to be conservative in attempting to tell what is likely to happen in any limited region or at any given time.

The one definite prospect for the immediate future is that there will be a considerable withdrawal of fuel from the home market for use in military operations. The quantity needed

Digitized by Google

can be conservatively estimated for the present calendar year at about a fifth of the total production of the country. There is a likelihood that the quality will also be changed in the direction of further decrease in volatility because gasoline for military purposes will necessarily be of higher test than the present average commercial grade. If the total production is to be kept up to the present market this will mean that domestic gasoline will be of lower volatility than now. In addition, refiners may be obliged to curtail their use of sulphuric acid, which will result in the marketing of gasoline of inferior color and odor.

The fuel situation is unfortunately one for which the ultimate successful termination of the war does not promise permanent relief. Estimates as to the number of years our resources of crude oil will last have been variously made and it is agreed that unless unexpected resources exist another generation will witness an actual shortage in the raw material from which gasoline is now produced. It is certain that the world cannot go on forever using up crude petroleum at the present rate of consumption and it is even now desirable to face this prospect squarely and make allowances for what the future is likely to bring. The possibilities of new supplies of fuel will therefore be discussed briefly, with the idea of showing the relative importance of the sources of relief mentioned.

Use of Alcohol

When looking for a future supply of any product it is natural to consider raw material that can be continuously produced instead of taken from a stored-up deposit. Alcohol is a volatile liquid fuel that is known to be satisfactory for use in internal combustion engines and which can be produced by the simple process of fermentation from any source of sugar. Unfortunately, however, evidence is still lacking that alcohol can be produced sufficiently cheaply enough to compete with various other forms of fuel that come to us as it were ready made. Just at present alcohol sells at a price that almost prohibits its use even as an anti-freeze compound. This situation is of course abnormal and there is every prospect that in the future alcohol may be on the market at a lower price than ever in the past.

The economical utilization of alcohol requires, however, engines that operate at compression pressures far greater than now employed for gasoline, which fact introduces complications that relegate alcohol to the far distant future as a potential substitute for gasoline. For the present it seems that alcohol is only of academic interest as an engine fuel except perhaps in localities where gasoline is expensive and scarce and the most promising raw material for alcohol manufacture is cheap. Such a situation already promises to develop in the Hawaiian Islands; gasoline is obtained there only after shipment over sea, but low grade unrefinable molasses is produced in large quantities.

Use of Coal-Tar Distillates

Another source of fuel that has received much attention is the by-product coking industry. The light oil constituents obtained by this process, such as benzol, toluol and xylol, are known to be satisfactory fuel, and although during the war the demand for them will continue to be greater than the supply, they will undoubtedly be marketed as fuel after the present abnormal production of explosives decreases. The use of these hydrocarbons either as such or blended with petroleum gasoline may increase the supply of fuel to a certain degree, but unfortunately the total available supply is relatively small. The following statistical information is interesting: The gasoline production of the United States for the calendar year 1916 has been variously given at from 2 to 2¼ billion gallons. The U. S. Bureau of Mines report on refinery operations for the year 1916 gives 2,058,880,596 gal. This includes a portion of the production of casinghead gasoline, which has been given as 104,212,809 gal. by J. D. Northrup, U. S. Geological Survey press bulletin No. 332 (August, 1917).

The production of coal-tar light oils for the same year was 36,600,000 gal. (C. E. Lesher, *Iron Age*, Vol. 99, Feb. 22, 1917), and it has been estimated that during the year 1917 this production will have been increased to from 40 to 60 million gallons. These figures indicate that if the total production of coal-tar light oils of the country were added to the engine fuel supply the increase would be about 2 per cent. These figures represent coking operations already conducted by the byproduct method. Figures based upon the total coke production of the country and even the total coal production of the country are not much more promising. The total coke produced in 1916 by both beehive and by-product ovens is given as 54,533,585 short tons and the total bituminous coal as 502,519,682 tons. (United States Geological Survey press bulletin No. 343, November, 1917). It is likewise recorded that the average yield of coke from a ton of coal is 1440 lb. and the average yield of light oil is 1.54 gal. (C. E. Lesher, Mineral Resources of the United States (1916) part 2, pp. 515-558).

Calculations from these figures indicate that if all the coke produced in the country in 1916 had been made by the by-product process the 75,741,053 tons of coal used would have yielded 117,641,232 gal. of light oil, which if entirely devoted to use in internal combustion engines would have increased the available supply of fuel by a little more than 5 per cent. If all the bituminous coal produced had been coked and had yielded the same average quantity of light oil as the grade of coal now used for coking the light oil produced would have amounted to 753,779,523 gal., which proves to be

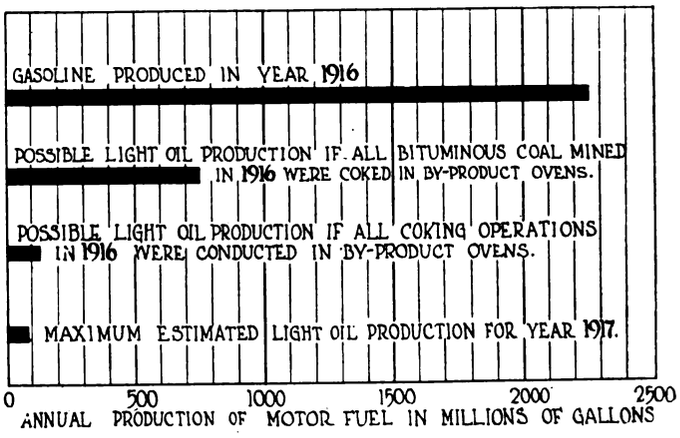

Fig. 3—Showing relative magnitude of present annual gasoline production of the United States and the additional quantities of motor fuel available from the distillation products of coal

less than 34 per cent of the gasoline production. These statistics show the limitations of the coking industry as a source of engine fuel. Fig. 3 represents graphically the theoretical quantities of fuels produceable from coal as compared with the gasoline actually produced. The use of coal-tar light oils as fuel will undoubtedly aid to increase the supply at some time in the future but they by no means promise to meet the total need for more gasoline.

It is by no means certain that tremendous quantities of crude petroleum exist that are not at present counted on, and producers are hopeful that such fields as the Mexican and even the Central American and South American fields may ultimately develop to a considerable degree of importance. The discovery of more crude would seem to be the easiest and most pleasant way of meeting the threatening fuel shortage, but this is a possibility that is so uncertain that it is hardly wise to place dependence on it.

Gasoline from Oil Shale

Vast deposits of oil bearing shale are known to exist in certain parts of this country and engine fuel can undoubtedly be obtained from this source. Here, however, as in the case of alcohol, the factor of expense in producing puts these products in the class of a resource that may be utilized in the future. Scientists are already giving attention to the problem of working up these shales and it is hoped that satisfactory methods for obtaining engine fuel in maximum quantity and of the best possible quality will be developed by

Digitized by Google

the time it becomes commercially practicable to use these shales. Many problems in the fields both of distillation of the shales and treatment and refining of the oils remain yet to be solved, but these problems are considered to be comparatively simple of solution and are now being studied.

From the point of view of the oil refiner the most desirable way of increasing the supply is to get more of it from the same quantity of crude oil now refined. This can be accomplished either by extending the range of volatility acceptable for fuels or by the employment of methods that increase the quantity of volatile products obtainable from the crude. The latter possibility is that which the use of the cracking process covers. The development of these processes is to-day the most important field of experimentation in the industry and considerable progress has already been made. The Burton process, owned and controlled by the Standard Oil Company of Indiana, and operated by various of the companies of the Standard group, has been developed to a high degree of efficiency and is regularly converting large quantities of heavy petroleum distillates into satisfactory fuel.

The Hall process, which is said to be operated on a large scale in England and to some degree in the United States, is also apparently in the stage of successful commercial operation. The Rittman process, with which the Bureau of Mines has been largely concerned, seems now to be thoroughly developed for the large scale production of gasoline and should soon be a commercial factor in the market. Other processes now operating are the Greenstreet and the Cosden.

Burton Process

At present it appears that the Burton process and others of the pressure distillation type can operate successfully using as raw material fairly heavy petroleum distillates, such as the fuel and gas oil types. The Burton process cracks a limited amount of kerosene also but it is not adapted in its present stage of mechanical development to the treatment of oils of this type. The Rittman and Hall processes are said to operate equally well with kerosene and the heavier distillates. The Greenstreet process seems to operate entirely with kerosene distillate. It is not known that any pressure cracking process is successfully utilizing oils of the residuum type in large-scale apparatus. These crack readily enough, but the mechanical difficulties incident to the deposition of large quantities of carbon have so far interfered with commercial success.

The general consensus of opinion of those qualified to judge is that the production of volatile hydrocarbons, satisfactory for use as engine fuel, can be brought about by many modifications of the principle of applying heat and pressure but that the cracking process in general cannot be made a commercial success unless handled with a high degree of scientific and technical skill and under carefully regulated economic conditions. In other words, although oil is easy to crack it is not easy to crack profitably. The oil cracking art is in many ways like the poultry business. Any amateur can convert grain and meat scraps into chickens and eggs but it takes more than interest and ambition to accompany this process by the accumulation of financial profit. Likewise, it is tolerably easy to make gasoline out of heavy oil but a totally different matter to keep the cost of the finished product satisfactorily below its market price.

It appears therefore that although the cracking process offers great possibilities of increase in the supply of fuel, this increase is bound to be in the way of a gradual development and in no way revolutionary. It is possible that if cracking processes were used to the full extent of their applicability the total production of gasoline from the quantity of crude oil now produced might be doubled. This increase cannot however be expected on the basis of reasonable possibility in less than ten years.

An adequate discussion of cracking processes would require more time than automotive engineers would wish to devote to even this vital subject and for the present the situation can be summarized by stating that this method of increasing the fuel supply seems just at present to be considerably more important than any or all of the possibilities discussed.

The possibilities of increasing our future supply of fuel have already been discussed from the points of views of several industrial divisions. It has been shown that the men in the producing end of the oil industry may help solve the problem by making available new supplies of crude petroleum. Scientists have the problem of making available the supply obtainable from oil shales.

The coal distillation and the fermentation industries may in the future supply greater or less quantities, and the refiners by the improvement of their present methods and the development of cracking processes can contribute enormously to the country's production. There remains for discussion the part that designers and builders of internal combustion engines have to play in increasing the potential supplies.

Increase in Engine Efficiency

It may seem presumptuous for a rank outsider in the gasoline engine business to suggest that one of the most important lines of activity for automotive engineers is to increase the potential efficiency of the engines they turn out. It actually seems, however, that there are tremendous possibilities in this line, not necessarily through increases in mechanical efficiency but by educating the public to demand and use automobiles that are essentially economical in consumption of fuel. There are now on the market types of cars that on average roads and grades can travel about 20 miles on a gallon of gasoline. Most of these cars are of low and moderate price and it appears that the majority of higher-priced cars get notably less mileage, this in some cases being as low as 6 or 8 miles per gallon.

Such a condition should not continue because if fuel, at any price, is not going to be available, the automobile business is bound to suffer. For this reason it seems that the designers and manufacturers ought to take this matter in their own hands, regardless of the present demands of buyers, and work out a reasonable standard of performance for all cars. For instance, cars might be built with the basic assumption that a two- or three-passenger car must travel 22 miles on a gallon of gasoline, a five-passenger car 18 miles and a seven-passenger car 16 miles. Some such standard of efficiency as this should be regarded as ironclad and all automobile design based upon it. Such considerations as speed and hill-climbing power should not be allowed to interfere with this matter of efficiency and the users will soon get over the idea that it is necessary to have 80-hp. engines in their cars when 30 hp. is sufficient to carry them at adequate speed anywhere they want to go.

Use of Less Volatile Fuels

Perhaps no phase of the fuel situation has so interested automotive engineers as the use of kerosene in place of gasoline. Present market conditions are such that kerosene is one of the cheaper petroleum products, and as it has already been demonstrated to work satisfactorily in internal combustion engines under certain conditions there has been a great desire to render it available for general use in automobiles. The Bureau of Mines has had called to its attention many devices for the utilization of kerosene but believes that mechanical development in this particular line is a mistake. The logical and reasonable way to utilize kerosene is not as such but as a mixture with the gasoline produced with it in the refining of crude oil. In other words, attention should not be given to the utilization of kerosene but to the utilization of petroleum distillates containing both the gasoline and kerosene fractions of crude oil.

In terms of the testing laboratory this means fuel of high endpoint and correspondingly lowered average volatility. Such fuels could be produced by the refiners with slight modification of their present methods and equipment, and their price should be somewhat less than the average price of gasoline and kerosene now marketed separately. The gain would be the simplification resulting from the production and handling of one instead of two products. The Bureau is not attempting to tell just how the problem of designing engines that can handle fuel of from 550 to 600 deg. Fahr. endpoint can be solved, but accomplishment of such an end ought not to be beyond the skill and ingenuity of engine designers, especially as they have already seriously undertaken the infinitely more difficult task of using straight kerosene.

No Spares on French War Trucks

Taxi System of Spares as Repairs in Truck Convoys Considered Best

By W. F. Bradley
Special Automotive Industries Correspondent

PARIS, Dec. 27—Even in technical quarters the impression prevails that army automobiles should be sent forth equipped with a stock of spares calculated on the basis of the requirements of an isolated car going on a trans-continental trip. Thus the suggestion is frequently made that the standard equipments should include spare valves and springs, brake liners, magneto and carbureter parts, gaskets, fan belt, etc. When the first taxicab services were started the cars were sent out with a very complete collection of parts. It was discovered that these parts were lost, broken, or ruined by rust; or if they were kept in condition the drivers did not possess the knowledge necessary to use them.

War Truck Drivers No Experts

War conditions have been similar. The average truck driver in the European armies is no better than the average taxicab driver. Although America has good raw material at her disposal, and has not actually had to train drivers on a big scale as it is done in England and France, the average technical ability of the men she is putting, or will have to put, on her trucks is not very much higher than that of her European allies.

At first sight the suggestion to send trucks forth on war service without any spare parts appears drastic: it is a suggestion which invariably meets with the opposition of skilled and experienced drivers, who being themselves capable of carrying out repairs consider that other men can do so also. The case is being considered of trucks working in convoy formation, or, if running isolated, being attached to some permanent group, and not of staff cars which are always more or less independent and away from a permanent base. On truck service, then, it may be taken that 80 per cent of the spare parts given out to be carried on the vehicles will either be lost or rendered useless at the end of 6 months.

Lists of parts are made upon the assumption that these particular parts will either break or wear out and will be needed to enable the car to finish its journey. Thus the most commonly accepted lists comprise fan belt, carbureter float, magneto carbons, brake liners, valves with springs and cotters, driving chains, gaskets, etc. Some makers and some military authorities have proposed the inclusion of ball bearings and clutch plates. Not one enlisted driver in a hundred is capable of replacing a ball bearing or taking down the clutch on the roadside. Even if they could do this it is more economical to get a tow home and carry out the job with the conveniences of a field workshop. Assuming that the list of parts is selected with the greatest care, it is probable that the greater percentage of the cars will be held up by the failure of some part which is not included in the equipment. The more complete the collection the greater the risk of loss and damage and

It has been proved entirely practical to send fleets of trucks into the field with no other parts than four plugs and gaskets, a few split pins, wire and adhesive tape. Indeed, carefully considered, this is all that any car or truck working with a group really needs for active service. The tool kit should be complete and should include all special wrenches for dismounting and adjusting any part of the car. There should be oil cans, syringes, funnel, a reserve of gasoline, oil, grease and kerosene; a collapsible water bucket should be on hand, but on most portions of the European front water is so plentiful that it is useless to carry it around. In making this recommendation it is being assumed, of course, that the motor is reasonably well cooled.

There are on war service in Europe thousands of trucks which individually do not carry any spare parts. They give good and reliable service without parts, and their operating cost is lower than if these parts were supplied. Such a system is only possible, however, with a really competent and energetic officer at the head of the column. It is a more difficult matter than is generally imagined to make automobile drivers give to their cars and trucks the attention necessary to keep them in good running condition. Unless kept under strict control the average army driver will not clean out oil filters, screw down grease cups, watch for loose nuts, take care of his battery, lubricate his universals, and do the other minor duties which are not repairs, but are essential if the car is to give continued satisfactory service. Responsibility for all this devolves on the officer in charge of the column or section; if he watches these points carefully the service will be good; if he neglects them the service is bound to be poor.

Supplies in Charge of Column Mechanic

Truck columns working on the principle of no spare parts aboard the individual trucks carry a stock of supplies in charge of the column mechanic. This stock comprises details such as bolts and nuts, split pins, spark plugs, gaskets, rubber hose, and the following:

- 1 magneto
- 2 radiators
- 8 valves complete with springs
- 16 valve cap gaskets
- 8 piston rings
- 2 connecting-rod bolts
- 2 carbureter jets
- 1 carbureter float
- 1 fan belt
- 2 fan belt fasteners
- 1 fan bearing
- 1 rear spring
- 1 front spring
- 2 rear-spring shackle bolts
- 2 front-spring shackle bolts
- Greasers

The parts are carried aboard a covered two-wheel trailer which travels with the column and remains at the column headquarters. Thus this trailer only covers a fraction of the mileage of any of the trucks, for it merely changes its quarters when the column moves its base. The mechanic attached to the column is personally responsible for this stock of spare parts and can be called on at any time to show what he has done

Digitized by Google

with them. The mechanic renews his supply from a park which is responsible for the maintenance of approximately 12 columns, or 240 trucks. The park gets its renewals from the base.

It has been found possible to considerably reduce the total number of truck and car parts kept in stock for vehicles on war service without any loss in efficiency. Thus a certain high-class American truck is composed of 1205 individual parts, according to the maker's parts catalog. One of the European forces has reduced these parts to 402 by refusing to stock such parts as are never known to break, or which are of such a nature that they can be made cheaper than they can be imported.

To give a few examples: Running-board brackets are eliminated; fenders, running boards, tops, subframe members, lamp brackets, are all considered unnecessary. Many bolts, nuts, washers, etc., common to all makes are cut off the list. Minor controls are eliminated. If any unit in the field sends in a request for one of the 603 parts not stocked because considered unnecessary, the applicant is informed that the part can be obtained on special order from America, and that delivery will be made in 6 months' time; under the circumstances it is intimated that an attempt should be made to make this part in the field workshop. Invariably the applicant discovers that he can make the part.

If true economy is to be studied, it is impossible to draw up a general list of parts to be stock and apply that list to all makes. Under European experience the parts stocked in the military bases, these parts, as already stated, comprising only about one-third of the parts figuring on the makers' catalog, are carefully studied for each make of truck and differ considerably in their details. To give a few instances without mentioning any names:

One truck is liable to fractures of the water collector on the head of the cylinders, while on another these are never known to break.

Truck A burns up valves occasionally and breaks springs.

Truck B, which is equipped with spare valves, hardly ever breaks or burns one.

Truck C has poorly designed water spaces around the valve seats and cracks cylinder from time to time.

Truck D—no cylinder ever has cracked except from frost.

Truck E, by reason of a peculiarity of its oil system, is liable to burn out one of the connecting-rod bearings. This never happens on Truck F.

Truck G has a very powerful transmission brake and under its influence unskilled drivers sometimes strip gears.

Truck H breaks driveshafts from time to time.

A certain model touring car is liable to fractures of the steering knuckle.

These are local weaknesses which have to be provided for in drawing up the lists of parts to be stocked, and are only given to show that uniform proportions throughout the automobile service will lead on the one hand to accumulations of dead stock, and on the other to vehicles tied up for lack of parts.

Another situation which has been found necessary to guard against very closely is the accumulation of stocks at various points in the service. The mechanics working on a column have need of one crown wheel. Unless controlled they will put in a requisition for six, using one and stocking the other five. A new cylinder being required, they will ask for a group complete with pet cocks, valves, springs, valve caps, fan bearing and brackets, etc., although all these parts may be available for use on the discarded cylinder. One American maker always ships his power plants complete in every respect, carbureter, magneto, fan, bolts for attaching to frame, etc. Whenever these are sent direct to repair units at the front the accessories are taken off and replaced by old ones withdrawn from the damaged engine, the new parts going to augment the stock, but without figuring on the stock list.

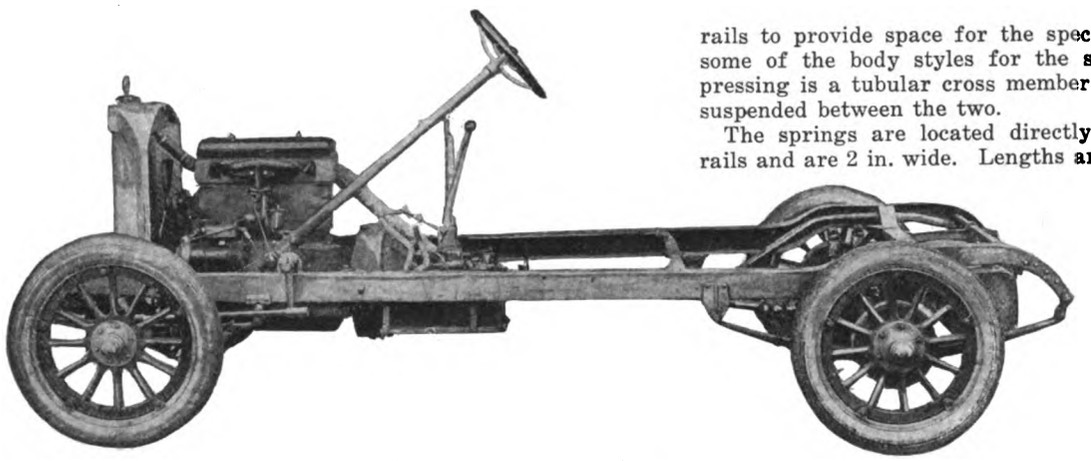
In order to avoid, as far as possible, all such accumulations of stock, the French service stipulates the parts and the quantities of such parts which can be kept, as follows:

1—On the truck.
2—In the hands of the column mechanics.
3—At the advanced workshop.
4—At the supply base.

Generally, before a new part is issued the old part must be returned, thus proving that the part is not being ordered needlessly with the object of getting together a little reserve stock. The same rule applies to tires: before a new shoe or casing is issued the old one must be presented. This has put a stop to the practice of leaving old tires by the roadside, and also prevents unscrupulous persons giving army tires away to friends.

Chromium Steels for Permanent Magnets

ALL high-grade permanent magnets used for industrial purposes have in the past been made of tungsten steel. This same steel is also used as tool steel, the well-known high-speed steel being a tungsten-alloy steel. In Germany, all tungsten was commandeered shortly after the outbreak of the war, by the government, and the electrical industries were then hard put to it in finding a substitute for their conventional magnet steel.



Experiments on the use of chromium in the place of tungsten, which had already been projected before the war, were accelerated. The research has been conducted in the Reichsanstalt on behalf of the Verband Deutscher Elektrotechniker. The preliminary report, published by the Reichsanstalt in 1917, did not give particulars, which were, however, to be communicated to members of the Verband on inquiry. Krupp's works supplied 37 specimens of steel containing varying percentages of chromium and of carbon; they had been turned into rods and hardened in various ways in the works, and were then aged, after the method of Strouhal and Barus, by repeated heating, cooling, and mechanical stress, while being tested at intervals in the Reichsanstalt.

The unfinished investigation concerns also the temperature coefficient of magnetization and the durability of the steels. It results that on an average chromium steels which have undergone suitable heat treatment do not rank below tungsten steels; the very best magnetic chromium steels, however, are not equal to tungsten steels. Technically, chromium steels would thus appear to be quite satisfactory, while for special researches their further improvement is desirable. These researches will probably be made in the near future.

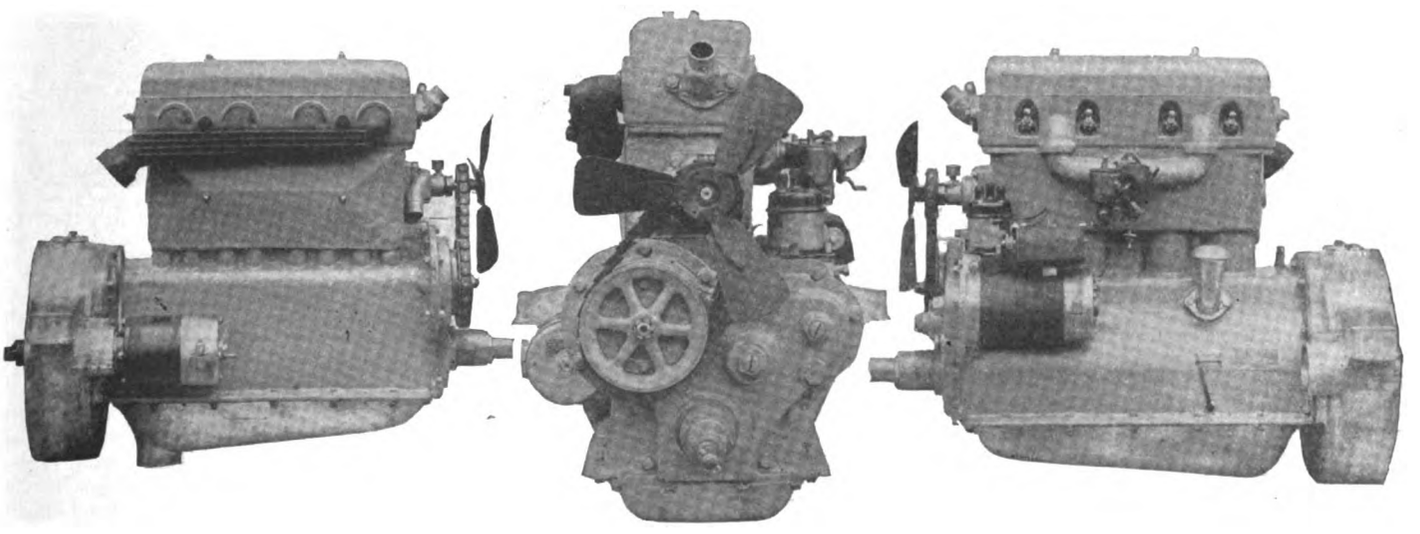
Mercury a Semi-Custom Car with Stock Chassis

Employs Weidely Overhead Four Cylinder Engine—Has Transmission Brake—Bodies Are Built to Suit Purchaser

Side view of Mercury chassis

MERCURY CARS, INC., at Hollis, L. I., are producing a car designed to meet the demand for a small automobile of high quality in chassis and body. The result is a semi-custom-made job in which the bodies are intended to fit the particular needs of the purchaser and to conform to his taste in color and style, while the chassis is a stock product. The price of the car, of course, will vary with the body selected, but may be judged by the fact that the four-passenger job, which is practically a stock model, sells for $2,950. The chassis has a 114-in. wheelbase and is mounted on 31 by 4-in. tires. With the small wheels the relatively short chassis fits well into the custom body scheme.

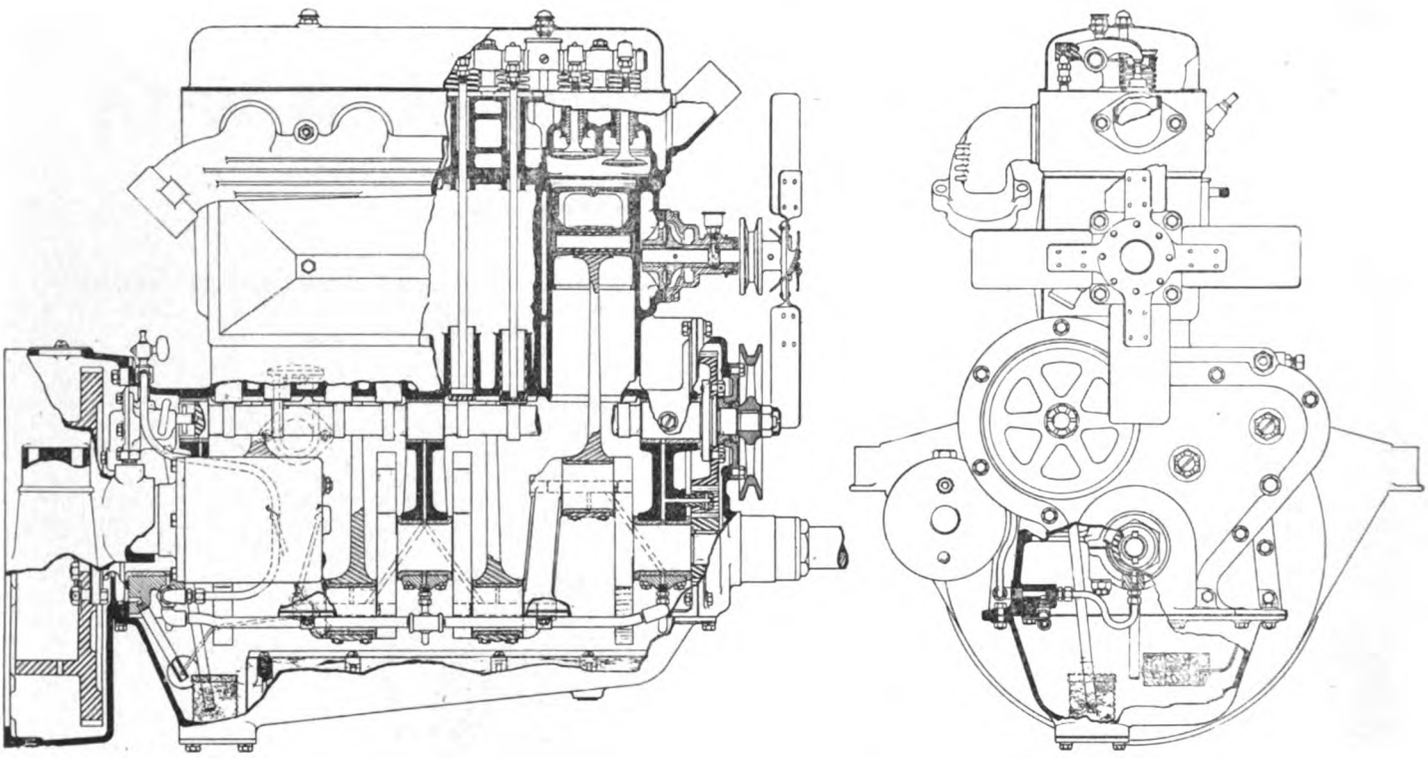
The frame is made of 4½-in. channel and tapers uniformly from front to rear. Being wide in the rear, it allows the weight of the body to be carried close to the wheels. It is provided with three pressed-steel cross members, the front member having a deep drop to support the forward end of the engine. The rear cross member is located below the side rails to provide space for the special mounting provided in some of the body styles for the spare tire. Back of this pressing is a tubular cross member and the gasoline tank is suspended between the two.



The springs are located directly beneath the frame side rails and are 2 in. wide. Lengths are 36 and 52 in. front and rear respectively. The rear springs are underslung. The springs are designed to be practically flat under load and are of chrome vanadium steel. Hotchkiss drive is employed and the spring eyes and bolts are provided with self-lubricating bushings, thus eliminating several grease cups, leaving 7 on the chassis.

The Weidely overhead, 3½ by 5½ in. four-cylinder engine is used in conjunction with a unit powerplant mounted with three-point suspension. The front spigot bearing rests in a pillow block bolted on the front cross member by a long U bolt and is provided with a self-lubricated bushing of impregnated wood. The two rear supports are cast on the bell housing in the form of arms which are bolted to the frame side members.

Brief Specifications



Cylinder number	4
Cylinder dimensions	3¾ x 5½ in.
Piston displacement	243 cu. in.
Clear valve diameter	1⅞ in.
Valve lift	5/16 in.
Crankshaft diameter	2⅛ in.

Lubrication, pressure feed to all engine bearings.

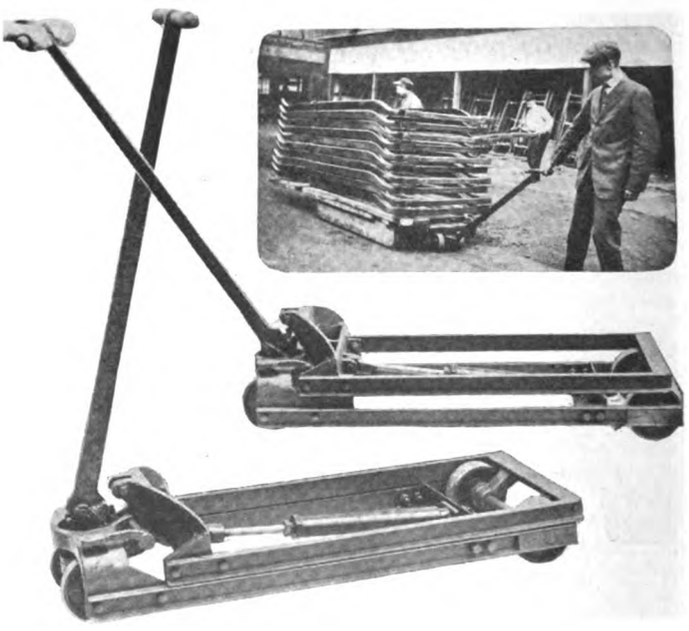
Three views of the Weidely four engine used on the Mercury car

Digitized by Google

Sectional view of the Weidely engine

Elliptic section connecting-rods are used and at the lower ends there are four bolts. The crankshaft has three bearings; it is of the counterbalanced type and is drilled for pressure oiling. The camshaft is driven through helical gears actuating the overhead rocker mechanism and the valves, which latter are 1⅞ in. diameter in the clear.

A feature of the engine is the unit casting employed for the cylinder block which also includes the intake manifold. With this arrangement the carbureter connections need not be disturbed when the cylinder head is removed. The exhaust-manifold is provided with integral cooling fins. The extension of the pump shaft carries the fan, which is driven by a V-belt. The radiator is a removable core type and has 5 gal. capacity; it is supported on a large sheet of cork within a shell of patented design. The shell is built up on a pressed-steel base so designed as to rigidly support the radiator construction and at the same time to provide the necessary flexibility to take care of weaving of the frame.



The electric system is a two-unit Delco with flange-supported motor and generator. The starting engagement is provided by a Bendix gear drive. Carburetion is by the new Stromberg Type M instrument and oiling is by a full pressure feed system through a hollow shaft. The drive is taken through an eleven-disk dry clutch faced with Raybestos, a three-speed gearset and a three-quarter floating spiral bevel rear axle with annular ball bearings throughout. There is only one set of brakes on the rear wheels, the service brake being a transmission unit of the external contracting type acting on an 8¼-in. drum mounted on the front universal joint. Adjustment of this is made easy by locating the thumb nut which controls it beneath a small trap door in the front floorboard through which the driver can control the application without leaving his seat. The rear brake connection consists of a single cable, and this simplification of the brake linkage has resulted in an exceptionally clean chassis.

Another feature of accessibility is the use of a second trap door providing access to the storage battery which is located beside the gearset on the opposite side from the exhaust pipe. The gasoline tank is of pressed steel, of 16 gal. capacity and is fitted with a 2 gal. reserve for emergency. Standard fittings on the car are a Boyce Moto-Meter, oil pressure gage, ammeter, 8-day clock, magnetic gasoline gage, Van Sicklen speedometer, combination lighting and ignition switch with Yale lock on hood and on dash compartment, all being operated by a master key.

The bodies are practically custom built, as stated, although of semi-stock design, the purchaser's ideas being carried out in regard to details. In the small four-passenger touring model which was exhibited at the Astor Salon, the space under the cowl is lighted and ventilated, three ventilators being provided for the latter purpose, two on the side and one above, this upper one, having a curved glass panel. The front seats are divided and adjustable to accommodate the driver. This body has two doors and has a locker at the rear which completely conceals the spare tire without producing the objectionable bulging back.

Industrial Trucks

In our Jan. 17 issue appeared a brief description of the Barrett multi-truck for moving material and products in industrial works. Below are shown several views of this truck.

Barrett multi-truck and its method of use

Chevrolet Company Adds Light Truck

Sold Either as a Chassis or with an Open or Covered Body—Has Worm Gear Drive

MORE and more of the companies manufacturing popular-priced passenger cars are turning their attention to the light truck field and bringing out models of commercial vehicles embodying the same power plant as their passenger cars. The latest concern to take this step is the Chevrolet Motor Co. of New York and Flint, Mich., which has just announced a 1-ton truck chassis to sell at $1,125. This same chassis equipped with an open delivery body sells at $1,245 and with an eight-post top and body at $1,320, all prices being f.o.b. Flint.

An interesting feature of the new car is that it has a full electric equipment, including both a starter and a lighting system. The frame is sufficiently long to carry a standard body with a clear loading space of 9 ft. 6½ in. and a clear inside width of 3 ft. 9¾ in. The large loading space of the body enables the vehicles to be used in almost every conceivable kind of business.

The truck is fitted with a valve-in-the-head type engine with a piston displacement of 224.3 cu. in. It is mounted under a conventional hood forward of the dash and is carried on arms extending to each side of the frame. The rear end is carried on two heavy malleable iron castings hot riveted to the frame and held in place by two drop-forged U-bolts. The front is hung in shackles bolted to the motor arms and to two substantial brackets hot riveted to the frame. The cylinders are cast in block and are provided with a removable cylinder head. Lynite pistons with three rings are employed and the crankshaft is carried on three main bearings.

The engine is water cooled by means of a centrifugal pump circulating the water through a cellular type radiator with a heavy brass core and a pressed steel casting. The radiator is mounted on two V-shaped slotted steel springs bolted to the front cross member and resting on two steel washers. A 15-in. pressed steel fan is employed and is driven by a V-shaped leather link belt.

A Zenith carbureter is used with a hot-air-jacketed intake manifold. The carbureter is fed by gravity from a 13-gal. tank located under the driver's seat. All the air enters the carbureter through a combined strangler and temperature regulator which provides a cold-air opening during warm weather. A Monarch suction governor is installed between the carbureter and the intake manifold to limit the speed of the truck to 25 miles an hour.

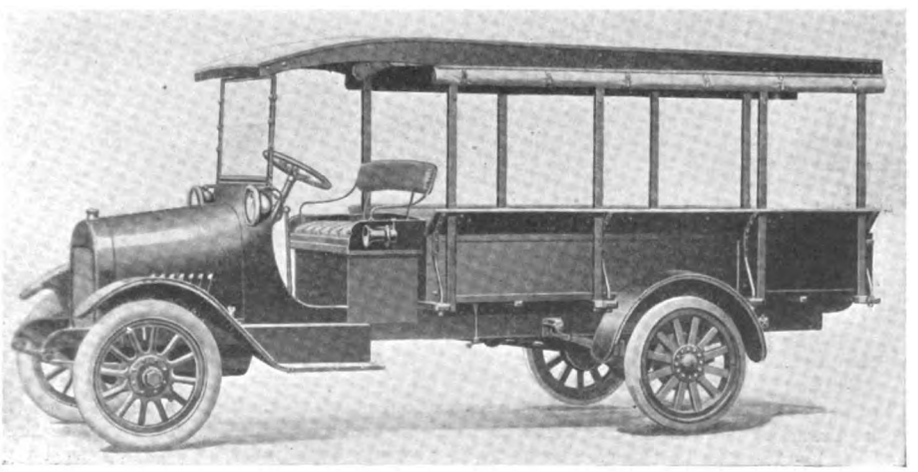
Ignition is by a Remy distributer. An Auto-Lite generator is employed and begins to produce a charging current at a vehicle speed of about 6 miles per hour. The electric starter is also an Auto-Lite product. It is mounted on the rear motor arm and operated through a Bendix drive.

From the engine the drive is taken through a cone clutch with a leather facing and thence to a three-speed selective gearset. The gearset is carried on a frame bolted to the flywheel housing, and can be quickly and easily removed, being located directly under the driver's floorboards.

From the gearset the drive is taken through a seamless steel tube propeller shaft with three universal joints to the worm-driven rear axle, of which the worm and worm gear are made by the Cleveland Worm & Gear Co. The rear axle housings are of malleable iron and the axle shafts are of the semi-floating type.

Hotchkiss drive is employed, both the torque and propulsion being taken through the springs. Two separate sets of brakes of the internal-expanding type are located on the rear wheels. Each brakeshoe is 14 in. in diameter and 2 in. wide. Both sets of brake rods are provided with turnbuckles conveniently located to take up all brake wear. The frame is of open-hearth rolled steel channel 4 in. deep, and is provided with three cross members.

The wheels are of the artillery type and have 12 hickory spokes, front and rear. The front wheels are fitted with Timken roller bearings and are provided with malleable iron hubs with flanges of pressed steel. For greater speed, pneumatic tires are employed in front and solids in the rear. Left steer and center control are employed.



The engine hood is of heavy sheet steel with three hinge rods. An anti-squeak is used on both ends of the hood to prevent rattling, and the sides each have seven louvres for better air circulation. The cowl is also of heavy sheet steel riveted in place and carrying the instrument board, on which are mounted the speedometer, carbureter choke, ammeter, oil pressure gage and the lighting and ignition switch. Passenger type front and rear fenders are used. They are of pressed steel in one piece and are crowned and attached to the frame side members by a heavy pressed steel V-section iron with a heavy sheet steel apron extending to the frame and completely inclosing the sides and protecting the runningboards from mud and water.

BRIEF SPECIFICATIONS

Load capacity	*1 ton*
Wheel base	*125 in.*
Cylinder number	*4*
Cylinder dimensions	*3 11/16 x 5¼ in.*
Piston displacement	*224 cu. in.*
Final drive	*Worm*
Torque and thrust on springs.	
Price of chassis	*$1,125*

Cost of Plowing in England

In the House of Commons recently, in reply to a question by Colonel Faber, Mr. Prothero stated that the average gross expenditure throughout England and Wales on motor plowing from spring to August last was 28s. 6d. ($6.92) per acre. This cost included work on the farm, traveling from place to place, labor, repairs and maintenance.

Specifications for Flexible Steel Wire Cable, Tachometer Drive from the Engine, Rubber Hose for Gasoline and Reels for Cable

The following table forms part of the specifications of flexible 6 x 7 steel wire cable printed in last week's issue of AUTOMOTIVE INDUSTRIES:

TABLE OF WEIGHTS, SIZES AND STRENGTH OF CABLE

Diameter, Inches	Minimum Breaking Strength, Pounds	Approximate Weight, Pounds per 100 Ft.
0.312 (5/16)	7,900	15.00
.250 (¼)	5,000	9.50
.218 (7/32)	4,000	7.43
.187 (3/16)	2,750	5.30
.156 (5/32)	2,200	4.20
.125 (⅛)	1,150	2.20
.109 (7/64)	830	1.50
.094 (3/32)	780	1.30
.078 (5/64)	480	.83
.062 (1/16)	400	.73

Flexible 7 x 7 Steel Wire Cable

S. A. E. Recommended Aeronautic Practice

This specification covers high strength 7 x 7 flexible steel wire cable used in the construction of aircraft where flexibility is important.

Manufacture—The steel wires composing the individual strands of the cable shall be laid concentrically around the center wire in one layer of six wires with a left-hand (counter-clockwise) pitch or lay. The cable itself shall be constructed by twisting six of these strands composed of seven wires each around a seventh strand of the same construction and material with a right-hand (clockwise) pitch and with a length of lay of six to eight times the diameter of the whole.

Wires composing the cable shall be uniformly coated with pure tin to solder readily.

Joints in wires in cable having a diameter of 0.156 (5/32) in. and larger shall be brazed in a gas fire. In cable having a diameter of 0.125 (⅛) in. or less, wires may be joined either by brazing or twisting, at the manufacturer's convenience. Tucked-in or welded joints are not permitted. No two joints in individual wires shall be closer to one another in the completed cable than 30 ft. All brazed joints shall be tinned. Exposed brass at joints shall not constitute cause for rejection.

Workmanship and Finish—Each length of cable is to be evenly laid, and free from kinks, loose wires, or other irregularities. The cable shall remain in this condition when unwound from the reel or bent around a standard thimble, proper precautions being taken to secure the ends.

Physical Properties and Tests—Tensile test—A tensile test shall be made upon each individual reel of cable purchased of a size.

Samples of cable for testing for tensile strength shall be no less than 24 in. in length. In making tests the distance between jaws of testing machine with sample in place and before test shall be not less than 10 in.

Samples for tensile test may be clamped in the jaws of the testing machine in the usual manner to facilitate testing; but in case of failure or dispute on individual tests and at the request of the manufacturer, check tests shall be made by socketing the samples with pure zinc.

Cable for use in the construction of aircraft shall meet the required breaking strength specified in the table.

Bend Test—One bend test is to be made on a sample cut from each reel of cable of a given size. Each sample must be bent once around its own diameter and straightened again at least 20 times in succession in the same direction of bending without any of the wires breaking.

Torsion Test—A torsion test is to be made on one wire from each sample of cable for tensile test. The wire is to be gripped by two vises 8 in. apart. One vise shall be turned uniformly at as high a rate of speed as possible without perceptibly heating the wire. One vise shall have free axial movement in either direction.

The number of complete turns which the wire shall stand is determined by the formula:

$$\text{Number of turns} = \frac{2.2}{\text{diameter in inches}}$$

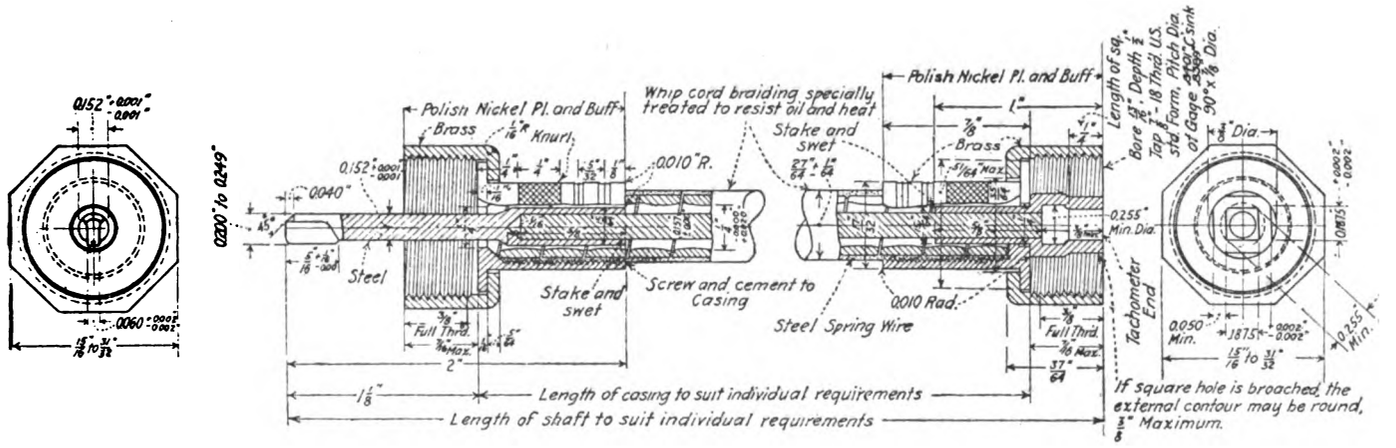
Failure of one piece of wire to show full number of turns specified in the above torsion test shall not be considered cause for rejection, but in such case two additional tests shall be made on two more wires from the same sample of cable, and if both samples meet the requirements of the specifications the cable shall be accepted in this respect.

Dimensions and Tolerances—There shall be no permissible variation in gage below size. Cable having a diameter of 1/16 to 3/32 in. inclusive, shall have a permissible variation of 12 per cent above size; cable having a diameter of ⅛ to 3/16 in. inclusive, shall have a permissible variation of 10 per cent above size, and cable having a diameter of 7/32 to ⅜ in. inclusive, shall have a permissible variation of 7 per cent above size.

TABLE OF WEIGHTS, SIZES AND STRENGTH OF CABLE

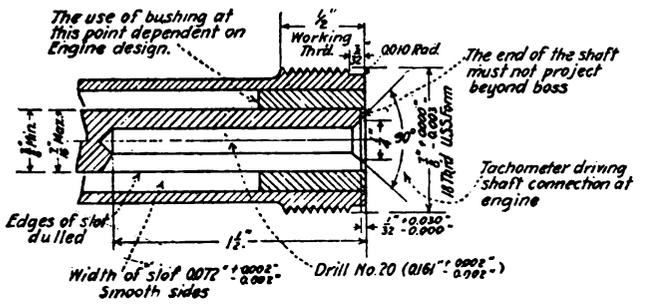
Diameter, Inches	Minimum Breaking Strength, Pounds	Approximate Weight, Pounds per 100 Ft.
0.312 (5/16)	9,200	16.70
.250 (¼)	5,800	10.50
.218 (7/32)	4,600	8.30
.187 (3/16)	3,200	5.80
.156 (5/32)	2,600	4.67
.125 (⅛)	1,350	2.45
.094 (3/32)	920	1.45
.078 (5/64)	550	.93
.062 (1/16)	480	.81

Extra Flexible 7 x 19 Steel Wire Cable



S. A. E. Recommended Aeronautic Practice

This specification covers high strength 7 x 19 extra flexible steel wire used in the construction of aircraft where extra flexibility is important.



Manufacture—The steel wires composing the individual strands of cable shall be laid concentrically around the center wire in one layer of 6 wires and another, or outer layer, of 12 wires with a left-hand (counter-clockwise) pitch, the lay or pitch of both layers being of the same length; the cable itself shall be constructed by twisting 6 of these strands composed of 19 wires each around a seventh strand of the same construction and material with a right-hand (clockwise) pitch or lay of 6 to 8 times the diameter of the whole.

It is to be understood that the strand composing this cable must not necessarily be composed of wires all of the same diameter.

Digitized by Google

Tachometer Drive

Wires composing the cable shall be uniformly coated with pure tin to solder readily.

Joints in wires in cable having a diameter of 0.187 (3/16) in. and larger shall be brazed in a gas fire. In cable having a diameter of 0.156 (5/32) in. or less, wires may be joined either by brazing or twisting at the manufacturer's convenience. Tucked in or welded joints are not permitted. No two joints in individual wires shall be closer to one another in the completed cable than 30 ft.

Workmanship and Finish—Each length of cable is to be evenly laid, and free from kinks, loose wires, or other irregularities. The cable shall remain in this condition when unwound from the reel or bent around a standard thimble, proper precautions being taken to secure the ends.

Physical Properties and Tests—Tensile test—A tensile test shall be made upon each individual reel of cable purchased of a size.

Samples of cable for testing for tensile strength shall be no less than 24 in. in length. In making tensile tests the distance between jaws of testing machine with sample in place and before test shall be not less than 10 in.

Samples for tensile test may be clamped in the jaws of the testing machine in the usual manner to facilitate testing, but in case of failure or dispute on individual tests, and at the request of the manufacturer, check tests shall be made by socketing the samples with pure zinc.

Cable for use in the construction of aircraft shall meet the required breaking strength specified in the table.

Bend Test—One bend test is to be made on a sample cut from each reel of cable of a given size. Each sample must be bent once around its own diameter and straightened again at least 20 times in succession in the same direction of bending without any of the wires breaking.

Torsion Test—A torsion test is to be made on one wire from each sample of cable taken for tensile test. The wire is to be gripped by two vises 8 in. apart; one vise shall be turned uniformly at as high a rate of speed as possible without perceptibly heating the wire. One vise shall have free axial movement in either direction.

The number of complete turns which the wire shall stand is determined by the formula:

$$\text{Number of turns} = \frac{2.2}{\text{diameter in inches}}$$

Failure of one piece of wire to show full number of turns specified in the above torsion test shall not be considered cause for rejection, but in such case two additional tests shall be made on two more wires from the same sample of cable, and if both samples meet the requirements of the specification the cable shall be accepted in this respect.

Dimensions and Tolerances—There shall be no permissible variation in diameter below size. Cable having a diameter of 0.125 (⅛) to 0.187 (3/16) in., inclusive, shall have a permissible variation of 10 per cent above size, and cable having a diameter of 0.218 (7/32) to 0.375 (⅜) in., inclusive, shall have a permissible variation of 7 per cent above size.

Tachometer Drive

S. A. E. Recommended Aeronautic Practice

Instrument End—The upper or instrument end of the shaft has a squared socket, made integral with a shoulder which forms a thrust bearing.

Engine End—The lower or engine end is finished with a cylindrical end with a single integral key.

Casing—The casing is to be of flexible metallic tubing, covered with whipcord braid and impregnated to prevent oil leakage; similar to sample, or covered with other material which will be equally flexible, oil tight and free from stretching and of no greater weight than the whipcord braid covering casing. The outside diameter of casing to be over braid to be approximately 7/16 in.; the inside diameter of casing to be approximately ¼ in. The ends of the casing are finished alike, as shown in detailed sketches. The screw-threaded sockets covering the whipcord braid are screwed in place and set with shellac or other suitable material to form an oil-tight and permanent connection.

Shaft End—The shaft end at the engine is drilled and slotted to fit the tachometer shaft end, allowing for end-play of at least 1 in. More play than this may be required where the drive shaft is more than 6 ft. in length, the amount to be determined experimentally.

Drive Shaft—Drive shaft to be of helical wire wound construction, with core wires.

Spindle—The tachometer spindle is finished square to fit the square socket on the drive shaft.

Drive Shaft—Drive shaft will rotate at one-half crank shaft speed.

End Nuts—Size and contour of exterior circumference of end nuts optional, but 15/16 octagon recommended.

Rubber Hose for Gasoline

S. A. E. Recommended Aeronautic Practice

COTTON PLY—TYPE No. 1

PART 1. TECHNICAL

A.—Description

Construction—The gasoline hose must consist of rubber and cotton constructed in the following manner, and the quality of the finished hose must be uniformly good throughout.

Digitized by Google

Inner Tube—The inner tube is to be made of rubber free from flaws or cracks and of a quality conforming to the conditions laid down in this specification.

When of an internal diameter of ¾ in. or less, this inner tube must be seamless. Tubes of larger internal diameter may be made from rubber sheet, in which case they must consist of at least two complete turns and be formed into a complete tube in the further process of manufacture.

Cotton Plies—The cotton shall consist of either braided or canvas plies and shall comply with the following table:

Internal Dia. of Hose	Up to and Including ⅝ In.	11/16 In. to 1½ In.	Greater than 1½ In.
Number of plies	Not less than two	Not less than three	Not less than four

Outer Cover—The outer cover is to be made of rubber of the same quality as that used for the inner tube, and of good workmanship and finish.

Dimension Limit—The internal diameter of the hose must not vary more than plus or minus 3 per cent of the internal diameter stated on the order.

Length of Hose—The contractor, when quoting or when acknowledging an order for this class of hose, must state the lengths in which it can be supplied. The hose should be supplied in the maximum lengths possible.

B.—Physical Properties

Flexibility—By "Flexibility" is meant ability to bend without kinking.

When hose of internal diameter (y) is bent around a cylinder having a diameter equal to x times the external diameter of the hose, as shown in the following table, the external diameter of the hose must not increase or diminish by more than 10 per cent.

Internal Diameter of Hose (y)	x
Less than ½ in.	8
½ in. to ¾ in.	12
13/16 in. to 1⅛ in.	14
Above 1⅛ in.	16

The hose, after having been filled with gasoline for two hours, must withstand a minimum internal hydraulic pressure of P pounds per square inch, depending upon the internal diameter (D) of the hose without showing defects.

D—Internal Dia. in Inches	Min. Pressure in Lbs. per Sq. In. (P)
Up to ½ inclusive	160
9/16 to 1 inclusive	140
1 1/16 to 1⅛ inclusive	120
1 9/16 to 2 inclusive	100
Above 2	80

C.—Chemical Properties

Rubber—The percentage of rubber shall not be less than 25. The amount of free sulphur in either the tube or the cover must not exceed 1 per cent.

Dry Heat Test—A 3-in. piece of the hose after having been placed in an air oven at 132 deg. C. for 2 hours, must show, when cool, no tendency to crack, and must not be tacky.

Permeability to Gasoline—The specific gravity of the gasoline used in this test should be between 0.710 and 0.725 at 60 deg. F.; 65 per cent of it must distill at over 100 deg. C. from a distillation flask when the bulb of the thermometer is just below the side tube. A 14-in. length of the hose is held vertically and plugged at the bottom. The upper end is fitted with a glass tube about 18 in. long. The hose so arranged is filled with gasoline to a head of 12 in. above the top of the acting length of the hose. The acting length of the rubber hose is 12 in. The upper end of the glass tube is loosely closed with a cork.

During the first 24 hours the level of the gasoline will fall comparatively rapidly. The loss of gasoline is made good by frequent additions from a known volume of gasoline, care being taken that the level of the gasoline in the glass tube does not fall at any time by more than 3 in. The test is to last for 72 hours, and the loss of gasoline during the third 24 hours must not exceed 100 cc. per square foot of the original internal surface of the hose.

Immersion in Gasoline—A 3-in. piece of the hose is boiled for one hour (using a reflex condenser) in gasoline similar to that used for the permeability test. The gasoline is allowed to cool down. Twenty-four hours later the test piece is removed from the gasoline and examined without delay, as follows:

The internal diameter at the point of greatest constriction is measured by means of rod gages. From this measurement the area of the bore is calculated. It must not differ from the original by more than 25 per cent.

The test piece is then cut longitudinally into halves, and the adhesion between rubber and cotton carefully examined. The adhesion must be of such a character that the rubber can only be stripped from the cotton by hand with difficulty.

Immersion in Oil—A 3-in. piece of the hose is immersed in an oil approved by purchasing office at a temperature of 100 deg. C. for 8 hours, and for a further period of 24 hours at ordinary temperature. The oil is then wiped from the surface of the hose. The decrease of internal diameter shall be less than 10 per cent.

The flexibility and elasticity of the rubber must not be diminished and there must be no tendency of the rubber to separate from the cotton.

PART II. INSPECTION

Test Pieces—The purchaser will decide where the tests are to be carried out. All test specimens are to be cut in the presence of the inspector and they are to be marked as he may direct.

For the purpose of testing, a representative sample will be cut from each 1000 ft. of hose or fraction thereof, and the tests will proceed in accordance with the purchasing office's instructions.

Rejections—If any sample fails to comply with any of the above tests, the hose represented thereby will be rejected.

Marking—Accepted and rejected material must be marked as directed by the inspector.

PART III. SPECIAL CONDITIONS

Depreciation—The contractor must bear the cost of the depreciation in value of any rejected material due to test pieces being cut therefrom.

Rejected Material—The contractor must not supply any material which has previously been rejected by any Government department, without giving full written particulars of the previous rejection to the inspector who is inspecting to this specification.

Rubber Hose for Gasoline

S. A. E. Recommended Aeronautic Practice

COTTON PLY REINFORCED WITH WIRE

TYPE No. 2

PART I. TECHNICAL

A. Description

Construction—The gasoline hose must consist of rubber and cotton constructed in the following manner, and the quality of the finished hose must be uniformly good throughout.

Inner Tube—The inner tube shall consist of a canvas tube supported by a helix of oil tempered steel wire of not less than .020-in. diameter, spaced not less than five turns per inch. The rubber tube shall be placed between this inner cotton tube and the cotton plies specified below.

Cotton Plies—The cotton shall consist of either braided or canvas plies and shall comply with the following table. The inner cotton tube shall not be considered one of the plies specified.

Internal Dia. of Hose	Up to and Including ⅝ In.	11/16 In. to 1½ In.	Greater than 1½ In.
Number of plies	Not less than two	Not less than three	Not less than four

Digitized by Google

Outer Cover—The outer cover is to be made of rubber of the same quality as that used for the inner tube, and of good workmanship and finish.

Dimension Limit—The internal diameter of the hose must not vary more than plus or minus 3 per cent of the internal diameter stated on the order.

Length of Hose—The contractor, when quoting or when acknowledging an order for this class of hose, must state the lengths in which it can be supplied. The hose should be supplied in the maximum lengths possible.

B. Physical Properties

Flexibility—By "Flexibility" is meant ability to bend without kinking.

When hose of internal diameter (y) is bent around a cylinder having a diameter equal to x times the external diameter of the hose, as shown in the following table, the external diameter of the hose must not increase or diminish by more than 10 per cent.

Internal Diameter of Hose (y)	x
Less than ½ in.	8
½ in. to ¾ in.	12
13/16 in. to 1⅛ in.	14
Above 1⅛ in.	16

The hose, after having been filled with gasoline for two hours, must withstand a minimum internal hydraulic pressure of P pounds per square inch, depending upon the internal diameter (D) of the hose, without showing defects.

D—Internal Dia. in Inches	Min. Pressure in Lbs. per Sq. In. (P)
Up to ½ inclusive	160
9/16 to 1 inclusive	140
1 1/16 to 1½ inclusive	120
1 9/16 to 2 inclusive	100
Above 2	80

C. Chemical Properties

Rubber—No organic matter other than Para or plantation rubber shall be used in the preparation of this hose. The percentage of rubber shall not be less than 25.

The amount of free sulphur in either the tube or the cover shall not exceed 1 per cent.

Dry Heat Test—A 3-in. piece of the hose after having been placed in an air oven at 132 deg. C. for 2 hours must show, when cool, no tendency to crack, and must not be tacky.

Permeability to Gasoline—The specific gravity of the gasoline used in this test should be between 0.710 and 0.725 at 60 deg. F.; 65 per cent of it must distill over at 100 deg. C. from a distillation flask when the bulb of the thermometer is just below the side tube. A 14-in. length of hose is held vertically and plugged at the bottom The upper end is fitted with a glass tube about 18 in. long. The hose so arranged is filled with gasoline to a head of 12 in. above the top of the acting length of the hose. The acting length of the rubber hose is 12 in. The upper end of the glass tube is loosely closed with a cork.

During the first 24 hours the level of the gasoline will fall comparatively rapidly. The loss of gasoline is made good by frequent additions from a known volume of gasoline, care being taken that the level of the gasoline in the glass tube does not fall at any time by more than 3 in. The test is to last for 72 hours, and the loss of gasoline during the third 24 hours must not exceed 100 cc. per square foot of the original internal surface of the hose.

Immersion in Gasoline—A 3-in. piece of the hose is boiled for one hour (using a reflex condenser) in gasoline similar to that used for the permeability test. The gasoline is allowed to cool down. Twenty-four hours later the test piece is removed from the gasoline and examined without delay, as follows:

The internal diameter at the point of greatest constriction is measured by means of rod gages. From this measurement the area of the bore is calculated. It must not differ from the original by more than 25 per cent.

The test piece is then cut longitudinally into halves, and the adhesion between rubber and cotton carefully examined. The adhesion must be of such a character that the rubber can only be stripped from the cotton by hand with difficulty.

Immersion in Oil—A 3-in. piece of the hose is immersed in an oil approved by purchasing office at a temperature of 100 deg. C. for 8 hours, and for a further period of 24 hours at ordinary temperature. The oil is then wiped from the surface of the hose. The decrease of internal diameter shall be less than 10 per cent.

The flexibility and elasticity of the rubber must not be diminished and there must be no tendency of the rubber to separate from the cotton.

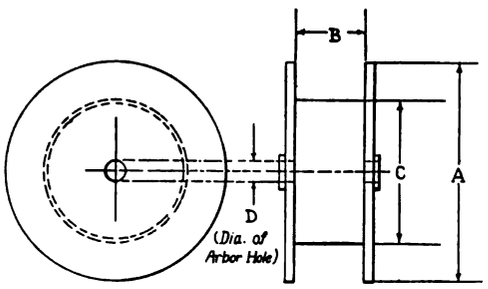
PART II. INSPECTION

Test Pieces—The purchaser will decide where the tests are to be carried out. All test specimens are to be cut in the presence of the inspector and they are to be marked as he may direct.

For the purpose of testing, a representative sample will be cut from each 1000 ft. of hose or fraction thereof, and the tests will proceed in accordance with the purchasing office's instructions.

Rejections—If any sample fails to comply with any of the above tests, the hose represented thereby will be rejected.

Marking—Accepted and rejected material must be marked as directed by the inspector.



PART III. SPECIAL CONDITIONS

Depreciation—The contractor must bear the cost of the depreciation in value of any rejected material due to test pieces being cut therefrom.

Rejected Material—The contractor must not supply any material which has previously been rejected by any Government department, without giving full written particulars of the previous rejection to the inspector who is inspecting to this specification.

Gasoline and the Coal Shortage

MOST of the country's present difficulties are traceable to insufficient transport facilities. The coal shortage is due to the lack of a sufficient number of cars and of locomotives to haul them, and the scarcity of coal is at the bottom of many other troubles.

Owing to the limitations of our transport facilities it is plain that no obstacles should be placed in the way of producers of means of transport, including both passenger and commercial cars. In speaking of means of transport in a national sense we generally have in mind only the railroads, but the automobile and motor truck are coming to be a very large factor in interurban transportation. According to the N. A. C. C. the passenger-miles of automobile travel last year was equal to the passenger-miles of railroad travel, which permits of the conclusion that the automobile relieved the railroad of a great amount of passenger traffic.

Similarly the motor truck. Previous to the war its field outside of urban haulage was limited to transportation between neighboring cities but under the stress of war conditions and as a result of the unprecedented congestion in freight traffic practically all distance limits have been removed, as indicated by the fact that trucks are used regularly for transporting tires from Akron to Boston. It is not claimed that the motor truck can compete with the railroad in this work on an economic basis. The question in this instance is not how to get the goods to their destination at the least expense, but how to get them there, and the motor truck furnishes the answer.

With the great demand for transport facilities motor trucks will undoubtedly be more and more impressed into long-distance service, and passenger cars will be limited to strictly utilitarian and necessary uses. Suggestions have repeatedly been made that automobile traffic should be limited legally in this country, the same as it has been in England and France, but such proposals entirely disregard the difference in conditions here and abroad. England and France cannot keep their automobiles going because they have no native fuel; all of their motor fuel must come from the United States or other countries still farther away, and as the shipping tonnage is taxed to the utmost by the more direct essentials, food and munitions, fuel cannot be brought across in sufficient quantity.

In this country there is no present motor fuel famine. All our oil wells are running and the refineries producing gasoline at a rate never attained before. Owing to the lack of storage facilities the gasoline must be used practically as produced. The widespread use of gasoline as motor fuel helps to greatly reduce the demand for coal and thus to relieve the coal shortage. Our civilization requires the use of great amounts of power. Millions upon millions of horsepower are produced in gasoline engines, and if we could not use these engines we should have to require a great deal more coal-consuming steam plant. Therefore, there must be no restriction on the production of motor fuel and on the rational use of same.

The Motor Boat Show

ANOTHER one of the automotive industries is this week holding its annual national show—the motor boat industry—in Grand Central Palace. Some pride is taken in the fact that in spite of the war a very creditable exhibition has been staged. True, the show is not as representative of the industry as were its immediate predecessors, but there are very good reasons for the absence of some well-known firms, which are so loaded up with Government orders that they had absolutely no inducements to bid for private business. Then, the list of small engine makers seems to be getting shorter year by year, probably because competition by the real manufacturers is proving too much for them.

Large engines of the six and eight cylinder types are becoming more numerous each year. The marine 8-cylinder engine is different from the "automobile eight" in that it is of the vertical type with all cylinders in line. There is not sufficient room in a boat for a 90 deg. Vee engine, while there is plenty of room in a lengthwise direction. All of these large engines are now provided with electric

Digitized by Google

starters and with an electric lighting system, the starters and generators being of exactly the same type as carried on automobiles, but in most instances of larger dimensions. The air starter of former years seems to have been entirely abandoned. The newness of this electrical equipment in marine practice is painfully evident in the makeshift mountings found on many engines. Undoubtedly a few years hence the electric starter and generator will be fully provided for in the crankcase design and not bear evidence of their installation having been an afterthought.

In engine design there is a tendency toward smoother exteriors and the complete enclosure of all moving parts. Enclosed flywheels are not new in marine practice, but this year they are more numerous than ever before. The lowering in the grade of fuel has confronted marine motor designers with the same problem as automobile designers and combination manifolds are beginning to make their appearance. In this respect marine engine practice seems to lag far behind automobile practice, which may possibly be explained by the fact that the average motor boat is used only in warm weather and its engine never needs to be started in a zero atmosphere.

Magnetos Retain Their Hold

In spite of the widespread adoption of electrical equipment marine engine builders faithfully adhere to the magneto for ignition. When battery systems are used they are merely auxiliaries for starting and for emergencies. Many large engines are provided with two point ignition and one even has four-point ignition, there being two two-spark magnetos and each cylinder carrying four spark plugs.

The unit power plant idea has secured a very firm hold in the marine engine industry. That is to say, the engine and reverse gear are now built into a single unit so that all chance of disalignment of bearings is eliminated. With the usual practice of having the flywheel in front this can be done without wasting material in a bell-housing, though, as stated above, flywheel housings are also coming into use.

Marine engine designers are also working toward more silent operation of their engines. To this end they are adopting helical gears for camshaft and accessories drives, enclosing the valve mechanism, reducing tappet clearances, lightening valve reciprocating parts, enlarging camshafts and giving them a better support by using larger or more advantageously located bearings. Owners of racing boats do not mind the noise, but on cruisers silent operation is as much appreciated as on a touring car.

It is a gratifying experience at each succeeding motor boat show to note how the obsolete, poorly designed and crudely built engines are gradually disappearing, and engines of better design and more workman-like finish are taking their place. The marine engine industry is in a state of evolution; real engineering is taking the place of rule-of-thumb methods and real manufacturing methods are superseding jobbing shop standards.

The Garabed

A MYSTERIOUS invention or discovery has been occupying the attention of Congress for some time now. Pursuant to a joint resolution adopted by both houses of Congress a demonstration is to be made by the inventor before a committee of five scientists, and in case the latter are convinced of the merits of the invention, the Secretary of the Interior will secure an assignment from the inventor for its exclusive use by the Government.

In the resolution the new device is referred to as a free energy generator. This term is entirely new. The law of the conservation of energy teaches us that energy, like matter, is indestructible—that it can neither be generated nor destroyed—and "energy generator" therefore is a rather radical term. Of course, we have power generators, but this is an entirely different thing, as power is merely a manifestation of energy.

"Free energy" is somewhat confusing; we suppose it is intended to mean energy without cost. As a matter of fact, all sources of energy at present in use are free in one sense or another. The wind that turns windmills and propels sailing vessels is absolutely free; the water of our great falls, from which so much power is derived, finds its way to the falls without human guidance and therefore occasions no expense. Coal and oil are stored away in the Earth's crust and need only to be brought to the surface.

It is in adapting these sources of energy to our particular needs that expense arises, and it then often turns out that what at first sight seems to be the least expensive of all powers is the most expensive when everything is considered. Take, for instance, the case of wind power, which on casual consideration seems absolutely free. Yet ships propelled by wind power have found it impossible to compete with steamers consuming coal that at the wharf usually has to be well paid for. Evidently, therefore, though the wind itself is absolutely free, wind power has not proved the most economical in this case, simply because with it not the same results are obtainable as with steam.

Just what claims the inventor makes for the Garabed we do not know—they are not disclosed in the house resolution—but unless the new source of energy at least equals coal and petroleum in its economical possibilities it will hardly play an important role in the engineering world.

Usually Congress is rather lethargic in giving recognition to scientists and inventors. Now that it has decided to give a special hearing to an inventor, who apparently claims to be able to supply power more cheaply than is possible by any known method, it is no wonder that the curiosity of the business world is roused to a high pitch, though those who have had extensive experience with inventors are still inclined to be skeptical. No one at all familiar with mechanical science looks for a solution of the so-called perpetual motion problem, a phantom that has been chased by inventors for centuries, and for which "free energy" seems to be only another less discredited name.

No Interference With Chicago Show

Neither Weather, Freight nor Fuel Will Seriously Affect Coliseum Exhibit

CHICAGO, Jan. 23—By telegram—The unprecedented weather conditions and the closing regulations of the Fuel Administrator are not going to interfere seriously with the annual Coliseum automobile show. It is probable that the show will be closed on Monday in accordance with the fuel regulations, although nothing has been definitely decided even at this date. It is probable that the building will be closed completely on Monday as well as on Sunday. There is a possibility, however, that the doors may be opened on Monday to dealers only, although the building will not be heated and possibly will not be lighted. Manager Miles intends to live up to the spirit and letter of the order and probably will not even burn the lights on Monday whether the doors are open or not. Inasmuch as the windows are completely obscured by decorations he feels little advantage is to be gained by opening the doors even to the dealer. The show therefore will be open to the public Saturday and from Tuesday to the following Saturday.

The tie-up of transportation is not seriously affecting exhibits, as a larger percentage of exhibits is now on hand than at this period of week before the opening in previous years. Manufacturers instead of sending all their cars from the New York exhibit to a greater extent have dispatched them from home factories, thus saving time and railroad charge.

Despite the traffic congestion, the fuel conservation order, and other abnormal situations, prospects for a good show from a business standpoint are bright. As usual the Chicago show will be the business show of the year and it is almost certain that it will exceed the recent exhibition in New York from the standpoint of business done and possibly also from the standpoint of attendance.

Decorations have a distinctly patriotic note, the feature of which is an art glass American flag 50 by 20 feet and flags of America and her allies from the main part of scheme of embellishment of the Coliseum. Of the 350 exhibitors 258 are displaying accessories and parts and 92 manufacturers are showing 400 cars and chassis. Three cars not shown at the New York exhibition will be on display—Comet, Pan-American and Maibohm. The Deering-Magnetic will be at the Salon. There will be more dealers' meetings and conventions than at New York, the most important of which is the war dinner at the Society of Automotive Engineers, at which 1500 people will be present.

Urge Use of Trade Acceptance on Government Work

NEW YORK, Jan. 22—The American Trade Acceptance Council, of which Lewis E. Pierson is chairman, is urging that authorities in Washington insist upon the use of Trade Acceptance by manufacturers doing government work. The council would like the government to adopt the policy of refusing to approve advance payments until the applicant has availed himself of his own credit possibilities by using the Trade Acceptance in the purchase of raw materials. It is pointed out that the government cannot itself pay for goods on the Trade Acceptance plan because of legal obstacles.

—

Government Help for Small Makers

DETROIT, Jan. 22—Small manufacturers in this vicinity who have been willing to go into war work but have not been able to finance themselves in changing over from their customary lines, have been informed that they will be financed by the U. S. Treasury. Lieut.-Col. Edward Clifford, one of the three members of the War Credits Board, is now here to describe such credit arrangements.

When a concern that has a contract for war supplies has shown the board that it needs financial assistance it will receive the money without delay, although the board does not act in any sense as a bank. Colonel Clifford states that it is only when the manufacturer has reached the point where financial assistance is needed in addition to his banking lines, that application for advance payment for his goods should be made to the board.

—

Detroit Will Recruit Motor Mechanics

DETROIT, Jan. 21—It is expected that a considerable percentage of the two regiments of motor mechanics needed by General Pershing will be recruited from Detroit. The Detroit Automobile Club is co-operating in securing the right kind of men for this work. The two regiments must be filled by Feb. 1. The request for these men was forwarded to H. G. Batchelder, executive chairman of the A. A. A.

Automobille mechanics capable of working on high grade gas engines are desired. About 60 per cent of the men will be made non-commissioned officers.

Fuel Situation Not Improved

Five-Day Shut-Down Fails to Relieve Shortage—Labor Problem is Serious

NEW YORK, Jan. 24—Following the general closing down of industries following Fuel Administrator Garfield's order, conditions are quieting somewhat and a canvass reveals that the order has not resulted in the increase in fuel that was hoped for and that freight conditions have not materially improved. Following are a number of telegrams which give the situation at the present moment:

DETROIT, Jan. 23—Net result of 5-day shutdown was diversion to domestic users of 105 cars of coal. In spite of this, unfilled domestic orders are 60 per cent more to-day than they were at the beginning of shutdown period. Besides this no headway has been made toward opening free passages for empty coal cars over roads south of Toledo, and all indications point toward a continuance and even an intensifyig of existig shortage.

Daily average of coal for 5 fuel holidays arriving in Detroit was 563 cars. This is about equal to normal conditions and showed that shutdown did not increase coal receipts as expected. Eighty per cent of coal coming through Toledo gateway is consumed in Detroit, remainder going to other sections of Michigan, so that all sections suffered proportionately. Needs of city are 700 cars daily, so that receipts have been 36 per cent below requirements. Detroit Edison Company, which furnishes most of plants with power, reported a saving of 40 per cent or 850 tons on Monday, as compared with normal days.

One of the biggest problems here has been to get the men engaged in war work back to their places. It was feared for a considerable time by plants which have been forced to close that the companies engaged in war work would hire the men who had been temporarily thrown out of employment by the edict, thus making them short in lines where there is an active demand for labor. This has not been done, however, to any extent.

Manufacturers are making every effort to speed up production in an effort to make up in some degree for the curtailment of the last 5 days, and it is very probable that big shifts of men will be employed on overtime work.

INDIANAPOLIS, Jan. 23—Conservative estimates to-day placed the number of men laid off from work in atomobile factories at from 2500 to 3000. As a result of exemptions from the order to companies engaged in manufacturing motors and trucks for army about 4000 men were kept working; about 3000 men engaged in work subsidiary to the manufacture of cars were laid off. The Weidley Motor Co., engaged in manufacturing motors for the Cleveland Tractor Co., and the Lyons-Atlas Co., engaged in manufacturing trac-

Automotive Industries

May Concentrate on Liberty Engine

Plane Building May Be Done Abroad—Doubt Efficiency of Drastic Fuel Order

WASHINGTON, Jan. 24—Howard E. Coffin, head of the Aircraft Production Board, in an interview yesterday stated that in the event of scarcity of tonnage the United States would manufacture only Liberty engines and parts, leaving to foreign governments the production of planes, for which they are well equipped. He also stated that the aviation departments of the United States Government which, only 3 months ago contained but 330 men, now include 90,000 men. Coffin states that excellent progress is being made with aircraft work and that planes are being supplied our men in France and England on foreign contracts.

The fuel order has aroused considerable speculation and several high officials who favored the order are now in doubt as to whether it has accomplished the hoped-for result. There are rumors that a similar order may be issued again in the near future for another five-day heatless, workless period. It is stated also that the single heatless Monday for the next 9 weeks may be curtailed by March 1.

Industry Calls Washington Conference

WASHINGTON, Jan. 24—There is to be a special meeting of the directorate of the National Automobile Chamber of Commerce and the Motor and Accessory Manufacturers' Association here to-day. The exact purposes of the meeting are unknown but it is understood that there will be conferences between representatives of the automobile industries with Director of Railroads McAdoo and Fuel Administrator Garfield.

—

Class AA Truck Nearly Ready

TOLEDO, Jan. 23—Special Telegram—The Class AA Quartermaster's truck which is being assembled here at the plant of the Willys-Overland Co. is completed except for the front and rear axles which are due to arrive from the American Ball Bearing Co., Cleveland, tomorrow. The engine and gearset are in and the frame is up on wood horses. Assembly was started two weeks ago and all parts are going together nicely.

—

Continue Copper Price at 23½ Cents

WASHINGTON, Jan. 24—The President has approved the recommendation of the War Industries Board that the maximum price for copper, which was fixed on Sept. 21 at 23½ cents per lb., be continued under the same conditions until June 1, when another revision may be made. Following the action of the War Industries Board on Sept. 21, copper producers met in New York on Sept. 28 and formed the Copper Producers' Committee on which is represented all copper producers. This committee is at present handling the entire distribution of copper, both foreign and domestic. In 1916 the amount of smelter copper produced was 1,942,776,309 lb. as against 1,888,395,945 in 1917, which is a decrease of 54,380,364 lb. Refined copper, on the other hand, increased in 1917 by 50,240,606 lb., the 1917 figure being 2,350,240,606 lb. as against 2,300,000,000 in 1916. Prior to the fixation of the price at 23½ cents copper had been selling at from 26 to 27 cents.

Joy to Retire from Lincoln Highway Presidency

DETROIT, Jan. 23—Henry B. Joy will retire from the presidency of the Lincoln Highway Assn., and it is rumored that F. A. Seiberling is slated as his successor. A meeting of the association will be held Saturday, at which the members will talk over the advisability of continuing road work in Utah and Nevada. Seiberling contributed $100,000 for this work, John N. Willys $50,000 and Carl Fisher $25,000.

—

N. A. C. C. Wants Better Export Service

WASHINGTON, D. C., Jan. 18—The National Automobile Chamber of Commerce through its general manager, Alfred N. Reeves, has asked for improved export service from the Department of Commerce. C. P. Carter, Assistant Director of Foreign and Domestic Commerce, in consequence, is arranging to provide more complete business information of all foreign countries to the automobile industry. Mr. Reeves is preparing a list of the kind of information required, including road conditions, financial conditions, gasoline supply, motor supplies markets, kind of people who may be secured as agents, methods of business as regards cash or credit, and so forth. As soon as this list is compiled Mr. Carter will secure the desired information and will endeavor in the future to frequently supply the industry with additional data along the same lines.

—

Church-Ward Leaves A-B-C Starter

DETROIT, Jan. 23—Alexander Church-Ward has relinquished his interest in the A-B-C Starter Co. and is no longer connected with that concern. At present he is engaged in consulting work of an electrical engineering nature.

Trucks Might Carry Ship Parts

Thousands of Vehicles Driven Overland Could Take Parts from 1600 Makers

WASHINGTON, Jan. 22—The thousands of war trucks to be manufactured in the great manufacturing zone of the Great Lakes might be utilized to advantage when being driven overland from that region to seaport to carry smaller parts needed in our ship building program. The original plan of carrying only spare parts in these trucks can readily be modified to embrace the urgent shipbuilding program.

For example: There are 200 companies in Detroit manufacturing parts of one kind or another that find a place in our ship-building program. In Michigan there are 400 such companies. There are more than 1600 in the five states of Michigan, Ohio, Indiana, Illinois and Wisconsin, all manufacturing small parts for shipping, and many of which might be transported overland in our war trucks.

It will be an example of that necessary war efficiency and co-ordination of efforts if co-operation along the following lines might be had.

The Quartermaster Corps instructs all its truck builders to direct the trucks en route to load and carry the parts needed by the shipbuilders.

The Highway Transport Committee creates routes so that the Quartermaster trucks can leave the various factories in which they are made, travel to the factories making ship parts and thence to the eastern seaboards with the least delay.

The trucks being manufactured for other divisions of the army exclusive of the Quartermaster Corps and including such as the Signal Corps trucks could also be used in such a plan as this.

The Shipping Board arranges with its manufacturers to deliver parts to Quartermaster trucks.

—

No New Liberty Engine

WASHINGTON, D. C., Jan. 22—The Aircraft Production Board declares that the story of a new Liberty motor which is being designed to surpass the present Liberty motor is entirely without foundation. The story has appeared in the general press throughout the United States and was to the effect that new mechanical innovations were to be used and that the present Liberty engine would be inferior to the new one. Howard E. Coffin says that the report is to be entirely discredited and has no foundation.

490,000 Vehicles in Great Britain

Scarcity of Fuel Puts 80% Out of Commission—Motorcycles Number 200,000

LONDON, Jan. 23—*By Cable*—There are approximately 490,000 motor vehicles in Great Britain to-day made up as follows:

Trucks, including delivery wagons	40,000
Automobiles	250,000
Motorcycles	200,000

These figures include vehicles in government use as well as those in private service. A considerable percentage of these vehicles are not in operation, due to the scarcity of fuel as well as legal restrictions. It is estimated that the percentages of these vehicles not in use, due to these causes, are:

Trucks, including delivery wagons	10% idle
Automobiles	80% "
Motorcycles	80% "

These figures are not official, but are the best estimates obtainable. It is difficult getting the exact figures because annual registration of vehicles is not required and hence there may be many so-called dead vehicles included in these figures. The percentages of vehicles not permitted to operate are substantially correct.

—

Detroit Sees Sales Boom

DETROIT, Jan. 19—Detroit's Seventeenth Annual Automobile Show, and in many respects the best ever held here, opened to-day in the new Overland building. Three floors have been utilized to display a very representative line of automobiles, trucks and accessories. There are 100 exhibitors, fifty of whom are showing passenger cars, twenty are showing trucks, and the remaining thirty, accessories. There are 230 cars on the floor. The show is held under the direction of the Detroit Automobile Dealers' Association and the exhibit space totals 75,000 sq. ft.

Detroit and the territory surrounding it is going to be one of the greatest buying centers in the United States during the coming year. It is estimated that due to war work the amount of money spent in local industrial establishments will be 300 per cent greater in 1918 than it was in 1917. Michigan, the automobile manufacturing center, has already taken a prominent place in the airplane industry, and under the spur of government needs for the prosecution of the war, great plans have already been established to manufacture airplanes and airplane parts, so that this state is well on its way to rank first in the United States in airplane production.

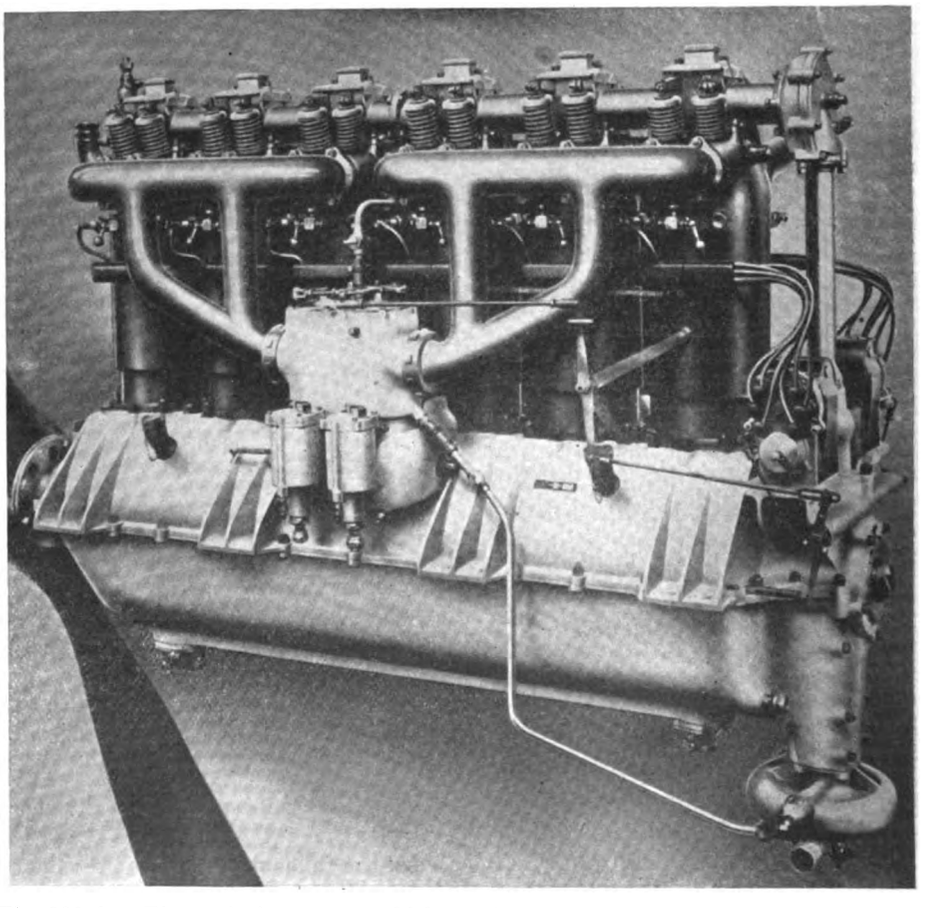
The Lincoln Motor Co. rapidly nearing completion, promises to be the largest plant in the country for the making of Liberty engines. The Ford Motor Co. is not only making in excess of 100,000 airplane cylinders, but is also making the Liberty engine complete. The furniture factories of Grand Rapids have recently pooled their facilities for the manufacture of airplane frames, and propellers. The Fisher Body Co. of Detroit is rushing to completion a 10-acre plant for the manufacture of airplanes and has already finished its first complete production plane. The Anderson Forge & Machine Co. is making crankshafts for the Liberty engine.

—

Factory Efficiency Discussed

CHICAGO, Jan. 19—The fundamental principles underlying factory reproduction and motion pictures illustrating the rigorous tests to which the Holt caterpillar tractor was subjected to by the various departments of the army, constituted last evening's program of the Mid-West section of the Society of Automotive Engineers.

F. A. Carlisle in his paper on "Efficiency in Factory Reproduction" contrasted the present-day methods and workmen with those of former years in regard to accuracy, speed, etc., concluding that the present-day workman was made more efficient than the old craftsman by reduction of waste motion, proper tools, less fatigue and in some instances even his social well-being was considered, all of which tend to promote speed and accuracy in production. In closing, the necessity of the planning department to facilitate production in the correct amount and at the correct time was discussed.



New Altitude Record Made by Italian

Lieut. Brak-Papa in Sia-Fiat Biplane Climbs to Height of 23,048 Feet

TURIN, ITALY, Dec. 22—On the military aerodrome in this city Flight Lieutenant Francesco Brak-Papa has established a world's height record with one passenger by climbing to an altitude of 23,048 ft. in 1 hr. 3 min. The machine, a Sia-Fiat biplane built in the shops of the Fiat Automobile Co., carried a useful load of 792 lb.

The climb was made at the following rate: 3280 ft. in 2 min. 30 sec.; 6562 ft. in 5 min.; 8942 ft. in 9 min.; 13,123 ft. in 15 min.; 16,400 ft. in 24 min.; 19,685 ft. in 37 min. 30 sec.; 21,325 ft. in 45 min., and the maximum height of 23,048 ft., as stated, in 1 hr. 3 min. The previous record, which was also held by Lieutenant Brak-Papa, was 21,161 ft.

The motor with which the record flight was made is a standard six-cylinder vertical Fiat with a cylindrical capacity of 1324 cu. in. and developing 300 hp. The motor has four valves per cylinder and direct mounted propeller. Cylinders are of steel with welded-on sheet steel water jackets. The same type of motor is used by the American army in France.

The 300 hp. Fiat aviation motor which established the passenger-carrying height record of 23,048 ft. in 1 hr. 3 min.

French War Trucks Aid Business

Army Convoys Carry Troops in One Direction and Merchandise in Opposite

By W. F. Bradley

PARIS, Dec. 22—In order to assist as far as possible to relieve the shortage of freight, the French army transport service undertakes the haulage of privately owned goods under certain circumstances. As examples, the town of Lyons, 300 miles southeast of Paris, receives large numbers of trucks and automobiles from the Lyons and Italian factories, and has to equip these vehicles and send them out to the front or to the neighborhood of the capital. It is now the general plan to send these truck convoys to Paris by road and to accept general freight for them. The public is informed from one to two weeks in advance of the departure of a convoy, the available tonnage, and the date of reception of the goods to be hauled. The price charged is 6 cents per kilometric-ton, packages not to exceed 141 cu. ft. each, and load to be not less than half a ton for any one destination or consignee. Goods are accepted for three towns en route, Chalon-sur-Saone, Auxerre and Fontainebleau. On reaching Paris the trucks go direct to the state aviation factory, where goods are unloaded. They must be called for at this place by the persons to whom they are consigned.

A similar system of public haulage by army trucks has been in force for some time between Havre and Paris and St. Nazaire and Paris, the respective distances being 120 and 250 miles. American trucks are used for this work. Formerly all these trucks were brought up by rail, then by road empty, for the army rarely had any freight to give them. By accepting commercial freight the railroads are relieved and goods are brought up with the least possible delay.

Modern Marine Engines at Motor Boat Show

NEW YORK, Jan. 22—The fourteenth annual motor boat show was opened here on Saturday last at the Grand Central Palace by the National Assn. of Engine & Boat Mfrs., of which John J. Amory is president. The exhibition occupies the ground floor and second floor.

Among the engines shown may be found all types from the small single cylinder outboard motor designed to be attached to canoes, to racing engines of over 300 hp., examples of the latter type being shown by the Duesenberg Motors Corp. and by the Murray & Tregurtha Co. In the Duesenberg exhibit is an eight-cylinder patrol model 360 hp. marine engine and a six-cylinder patrol model 260 hp. marine engine; the Murray & Tregurtha Co. exhibit a 300-400 hp. six-cylinder engine with double valves in the head. The latter has a bore of 7¼ and a stroke of 9 in. and is fitted with two two-spark magnetos and with four spark plugs in each cylinder.

A considerable number of marine engine manufacturers and motor boat builders are engaged in Government work on submarine chasers, motors and equipment of various sorts, and some of the engine builders also are manufacturing aircraft engines. The Duesenberg Co. shows two types of airplane engines, the four-cylinder type already described in these columns and a twelve-cylinder 300 hp. type.

French Engineers Plan Congress

To Be Held at the Sorbonne, Paris—Paper on Industrial Questions to Be Read by Lumet

PARIS, Jan 3—The civil engineers of France are to hold a congress at the Sorbonne, Paris, in March. The third section, which covers the entire question of transportation, has one sub-section dealing with the automobile industry. M. Lumet, who before the war was engineer of the laboratory of the Automobile Club of France, and who will be remembered as the first officer sent to America to purchase army trucks for the French forces, will present a paper dealing with "Industrial Questions: Manufacturing, Standardization, Methods of Work and of Production." Henri Cezanne, who in peace days was general manager of the Paris Automobile Salons, and is still general secretary of the French Automobile Manufacturers' Association, has been scheduled to read a paper entitled "Commercial Questions: Sale, Exchange, Customs Duties, Taxes, Production Combines."

Other papers will be read as follows:

"Best Methods of Developing the Use of Internal Combustion Motors in the Merchant Marine Service," by M. Lumet.

"Formation of Engineers and Technical Employees for the Aviation Industry," by Colonel Roche.

"Aviation Motors," to be dealt with by a commission of which M. Soreau will be the president.

"The Possibilities of Aviation After the War," by Colonel Espitallier.

French automobile column traveling by road from the French to the Italian front. Note that each truck has a trailer. In every convoy of 20 trucks one trailer is a workshop and another a kitchen

Canada Has 199,302 Cars and Trucks

1917 Figures Show Great Increase in Registration, Trade and Capital

MONTREAL, Jan. 21—There are now registered in the Dominion of Canada 199,302 cars and trucks. In several of the Provinces registrations are closed on Oct. 1, and in others the figures will be somewhat increased when full returns are available. There is owned and operated in Canada one car for less than 40 of population, as compared with a ratio of one to 60 shown by last year's figures.

The sale of cars in Canada during 1917 has been marked by a more general distribution throughout the country than in any previous year. Particularly in the West has this been noticeable, but it is apparent that all rural communities have been large buyers, whether due to the increasing measure of prosperity enjoyed by the farming classes, by the intensified good roads propaganda or by the general campaign of motor car education.

There were brought into Canada during the first 6 months of the present fiscal year, April to September, 1917, inclusive, motor vehicles, parts and tires, to the value of $13,144,405. This compares with a total of $17,056,685 for the fiscal year ending with March, 1917, but it will be seen that the imports of passenger cars in the 6 months almost equalled those of the entire preceding year, while the value of commercial vehicles brought in almost doubled, and that of tires imported showed a marked increase.

The record of exports shows a more uneven tendency, the volume for the first 6 months of the fiscal year ending March, 1917, being but slightly in excess of that for the year ending March, 1915. The 12 months ending March, 1916, showed the greatest activity in the Canadian export trade, the figures then going over the $10,000,000 mark, and very closely approximating the value of imports during the same period. The increasing difficulties of transportation, however, seriously interfered with the development of this branch of the business with the result that the succeeding years show a pronounced falling off in the volume of trade.

AUTOMOBILE REGISTRATIONS IN CANADA

1914	31,724	7,413	544	1,260	30	7,001	8,027	4,728	6,688	67,415
1915	42,346	10,112	971	1,900	35	8,812	10,225	5,832	7,440	87,673
1916	54,375	15,347	1,728	2,986	50	11,953	15,600	9,703	8,576	120,318
1917	84,353	21,702	5,678	5,249	301	17,333	32,500	20,800	11,386	199,302

Definite figures as to the value of the product of Canadian automobile factories are not available since 1915, but an interesting comparison illustrating their growth may be had from the statistics of the Government census of 1910 and the special business census taken in 1916 for the preceding year. This is given in the following table:

Factories.	1910	1915
Establishments	8	8
Capital	$361,272	$3,540,441
Salaries, wages, etc.	903,349	3,427,146
Cost of materials...	3,808,139	16,739,643
Value of product...	6,251,885	24,357,627
Repairs, Accessories, Etc.		
Establishments	11	120
Capital	361,272	3,540,441
Salaries and wages.	76,060	1,152,585
Cost of materials ..	40,893	2,434,197
Value of product....	170,930	4,329,938

There are now 12 automobile factories in operation in the Dominion, and while the number of accessory manufacturers can only be estimated, it is worthy of note that their growth has been most marked during the past three years, and they are now believed to be supplying 20 per cent of the total demand for automobile supplies and equipment within the Dominion. This is, of course, outside of the tire business, which is now almost controlled in Canada for the Canadian trade.

Few Separate Records

Consideration of the manner in which the motor truck business has grown in Canada is rendered difficult by reason of the fact that few of the Provinces have, in the past, kept separate records of the passenger and commercial car registrations. The first record in Ontario is for the year 1916, when 2786 trucks were reported, but this has been increased in the present year to 4590, showing a percentage of increase almost identical with that in the case of passenger cars. Quebec also shows a steady growth in the number of commercial cars registered, having had 384 in 1914, 528 in 1915, 729 in 1916, and 1080 in 1917, so far as has been reported. As in the case of Ontario, the truck registrations are in the neighborhood of 5 per cent of the total, so that it may be assumed that Canada has no less than 10,000 trucks in operation.

The commanding position occupied by the Province of Ontario in the motor car trade is evidenced by the fact that almost one-half of the total registrations are credited to this Province. Perhaps a pronounced factor in this situation is that all of the twelve companies now engaged in the manufacture of automobiles in Canada are located in the Province, and this fact has also served to attract by far the greater proportion of accessory manufacturers. The progress of the good roads movement has also rendered Ontario a very fertile field for the automobile agent, and rural communities have of late become very liberal purchasers.

The City of Toronto is credited with having 17,500 cars in operation, Hamilton with 5000, Ottawa and London with 3000 each, and Windsor with 2500. Outside of these large centers, the distribution is considered to be very even throughout the Province.

In the matter of percentage of increase for the year, the little Province of Prince Edward Island has the lead, having six times the number of cars it had in 1916, when only fifty were registered. This was, of course, due to the oppressive regulations, it being permissible to use cars only on certain days of the week and only on certain roads. But the breaking down of prejudices has been working gradually, and there are now 301 cars on the island, including six motor trucks.

The prairie provinces have also showed up remarkably well, the prosperity of the farmers being responsible for doubling the number of cars in Alberta and Saskatchewan. Manitoba has made almost a 50 per cent increase, while British Columbia has added about 35 per cent to its quota.—*Toronto Globe.*

Receiver Named for Bijur

Assets Exceed Liabilities by $1,100,000—Expect Quick End of Receivership

NEW YORK CITY, Jan. 18—A receiver was appointed to-day for the Bijur Motor Lighting Co., manufacturer of Bijur starting and lighting apparatus, this action being taken by Jos. Bijur, president of the company, after discussing the affairs of the organization with the major creditors. A committee of three receivers has been appointed, and the factory is being operated under this committee. Before the receivership action was taken, a meeting of the creditors, representing merchandise interests, was held, and this committee was of the opinion that the best interests of the creditors would be served by continuing the business, because the balance sheet shows that the company is solvent. The present difficulty, in the opinion of the creditors, has arisen from a large expansion of business, and a lack of working capital.

During the last 4 or 5 months the company has made heavy purchases of machinery, all of which is installed, being operated, and largely paid for. Perhaps the heaviest handicap the Bijur company has had to contend with is the merchandise account, which, in the condensed statement issued by the committee, is placed at $840,652. A year ago the merchandise on hand did not represent one-half this amount, or was $440,000 less than at present. The heavy merchandise account at present is due to reduced shipments of starting and lighting apparatus due to the slack in automobile manufacture. The Bijur company, while accommodating its customers by slowing up shipments in response to their requests, had contracted for its materials at advantageous prices and received them on regular schedule.

Besides several million dollars' worth of back orders for their regular equipment for automobile manufacturers, the Bijur company has orders for thousands of generators for the U. S. war trucks, and large contracts for miscellaneous articles for the Navy and Ordnance Departments. The factory is being continued at normal production on all of its domestic and Government orders. Inasmuch as the present assets of the company exceed the liabilities by $1,100,000 and at the time of its receivership the company had over $200,000 in the bank, and as the business has shown an increasing profit every quarter since its beginning in 1910, the last quarter of 1917 showing the largest profit in the history of the company, it is expected that the receivership will be of short duration.

The receivers appointed by the Court are: Joseph Bijur; Louis V. Hubbard, president of the Taft Pierce Co., Woonsocket, R. I., a director in several banks, and representing the banking interests; and E. B. Wilson, attorney, New York City, representing the creditors.

The Bijur plans for expansion were started in November and December, 1916, and included a new factory, which tripled the previous capacity, new machinery, which was four times greater than the previous amount used, and corresponding increases in organization to care for this expansion, and which was justified by the ability of the concern to execute orders offered to it. The factory was finished March 1, 1917, and is now operating with a force of 1100 to 1200 men as compared with 300 to 400 a year ago.

—

Stutz Earns $1,074,778

NEW YORK, Jan. 24—Stutz Motor Car Co. in the year ended December 31 earned net profits of $1,074,778, an increase of 65.6 per cent over 1916.

Output of cars in 1917 was 2207, compared with 1535 in 1916, 1079 in 1915, and 649 in 1914.

Output in 1917 increased 43 per cent, and it is officially stated that the entire maximum output for 1918 has already been sold.

Balance sheet as of Dec. 31 shows current assets of $1,455,098, compared with current liabilities of but $352,912, or a net working capital of $1,102,186. Net quick assets alone, excluding plants, equipment and good will are equal to $14.70 a share. Total selling, administrative and general expenses for the year were but $77,637.

Comparison is made below of the results for the calendar year 1917, with the seven months period ended Dec. 31, 1916:

	1917	1916 7 months
Net sales	$4,483,315	$1,771,328
Cost of manufacture	3,375,980	1,374,066
Gross profit	1,107,334	397,261
Selling and gen'l exp.	77,637	44,747
Balance	1,029,697	352,513
Int. and dis. earned	45,081	28,547
Net profit	1,074,778	381,061

Comparison of the balance sheet as of Dec. 31, 1917, with that of Dec. 31, 1916, follows:

ASSETS

	1917	1916
Fixed assets	$2,560,731	$2,431,603
Cash	252,811	74,059
Receivables	53,816	145,530
Inventory	1,148,470	577,248
Total	$4,015,829	$3,228,441

LIABILITIES

Payables	$317,462	$356,980
Deposits on cars	35,450	17,700
Taxes	6,000	8,500
Reserves	*59,491	31,329
Surplus	3,222,425	2,439,021
Capital at $5	375,000	375,000
Total	$4,015,829	$3,228,441

*Reserve to meet Federal taxation not included, as the amount has not yet been definitely determined.

Seigle Vice-President of Johns-Manville

NEW YORK, Jan. 22—At the annual stockholders' meeting of the Johns-Manville Co. yesterday, William T. Klauss was elected a director. Other directors were re-elected. At a subsequent meeting of the board of directors W. R. Seigle was elected vice-president. Other officers remain the same.

War Committee for Rubber Trade

To Be Point of Contact Between Government and Industry—B. G. Work, Chairman

NEW YORK, Jan. 22—The Rubber Assn. of America, Inc., has appointed a War Service Committee, representing the entire industry, with the following members: B. G. Work, president of the B. F. Goodrich Co., Akron, chairman; H. S. Firestone, president of the Firestone Tire & Rubber Co., Akron; James N. Gunn, president of the United States Tire Co., New York; G. B. Hodgman, president of the Hodgman Rubber Co., New York; and P. W. Litchfield, vice-president of the Goodyear Tire & Rubber Co., Akron.

Some of the functions of the war service committee will be to act as a point of contact between the industry and the Government; to supply information as to the ability of the industry to serve the needs of the Government in carrying on the war; to supply statistics regarding rubber; to co-operate in the standardization of specifications and products for Government use; to assist in the speedy and efficient production of Government requirements, and to put before the Government the needs of the industry at all times.

To help carry out these functions subcommittees will be formed to represent the various branches of the industry. Among these will be committees on pneumatic tires, solid tires, mechanical goods, medical goods, boots, aircraft, gas defense, reclaimed rubber, hard rubber goods, crude rubber and kindred products, foreign trade, statistics, supplies and reports. There will be technical as well as commercial committees on the various sub-divisions, to insure a balance of attention.

Bosch Must Pay Rushmore $100,000

NEW YORK, Jan. 21—The Bosch Magneto Co. has been directed to pay Samuel W. Rushmore, inventor of the Rushmore starter, $100,000 for breach of contract in that the Bosch company failed to use the name "Rushmore" in its advertisements of Rushmore starters. According to the contract, the Bosch company was to describe the starter sold as the "Rushmore Starter" or the "Bosch-Rushmore" starter or "System Rushmore," failure to do so involving a penalty of $100,000. Judge Hand has decided that the Bosch company broke its contract and ordered it to pay Rushmore the $100,000. The Bosch Co. will appeal the case.

—

Dayton-Wright to Build

DAYTON, OHIO, Jan. 23—The Dayton-Wright Aeroplane Co. will start work shortly on a factory 300 by 600. The structure will be 2 stories and will cost $200,000.

Boston Would Solve Freight Tangle

Propose 2 Weekly Trains to New England — Discuss Show Postponement

BOSTON, Jan. 19—The possibility of putting the Boston Motor Show back to the last week in March instead of the first, and a plan to have a committee of The Boston Automobile Dealers' Association handle two trains weekly from the motor centers carrying cars and trucks, were discussed at a meeting of the Board of Directors of the organization yesterday. After a full discussion of the matter it was voted that unless something extraordinary happened the present dates would be adhered to, but provision was made for a change if it seemed advisable.

The other matter was outlined by President MacAlman. He stated that he had been informed that there was a possibility of the government shutting down on all shipments of motor cars and trucks from factories to dealers. In addition to that there was talk of a transportation chief being placed in the motor centers to see that every motor vehicle leaving a factory carried something along in the way of parts, tires, etc. In other words, nothing would be allowed to move unloaded. As the government talked of taking over the express companies that avenue would be shut off.

Therefore he offered for discussion the suggestion that the organization consider a plan whereby it would appoint a committee to work with the transportation committee of the Boston Chamber of Commerce and try to have two trains weekly brought to Boston carrying motor cars and trucks. The committee would pledge the government to unload the vehicles on arrival so the freight cars would be available for return shipment immediately.

To Help Government

It was pointed out that this would be a means of aiding the government. If the trains could not be brought to Boston the committee would be satisfied to have them stop at Albany, and men would be there to take care of the unloading. Under the plan the dealers wanting cars would have to deposit with the motor committee the money to release the cars on arrival. No attempt would be made to play favorites, and the requests for space in the trains would be granted according to the receipt of application. The dealers would be given such space as would allow the greatest number to get some cars regularly instead of any one company to get a large number in one shipment.

As Albany is like the neck of the bottle leading to New England, it was felt that perhaps the government would be willing to go as far as that city with trains. By getting at least two a week through it would be possible to take care of a large number of dealers all through the territory.

—

Haynes Prices Increased

KOKOMO, IND., Jan. 19—Factory prices of all Haynes models have been increased as follows:

Model	New Price	Old Price
39—4-pass. roadster (formerly Model 37)	$1,825	$1,725
38—5-pass. touring (formerly Model 36)	1,725	1,595
39—7-pass. touring (formerly Model 36)	1,825	1,725
39—Sedan (formerly Model 37)	2,585	2,390
44—7-pass. touring (formerly Model 41)	2,785	2,295

In addition, the following new models are being built:

Model	Price
44—Sedan (12 cyl.)	$3,385
44—Coupe (12 cyl.)	3,335
44—Town car (12 cyl.)	3,985
39—Coupe (6 cyl.)	2.535
39—Town car (6 cyl.)	3.250

The prices of all touring models will be increased an additional $125 on March 1. Cars leaving the factory up to that date will be charged for at the present rate, but after March 1 even if ordered in advance, the new price will hold.

—

Fuel Situation Not Improved

(*Continued from page* 240)

tors, received notice of exemptions from the closing orders late Monday.

KANSAS CITY, Jan. 24—Ford assembling plant shut down Tuesday and Wednesday for lack of material. Two hundred and fifty men idle without pay; no shutdown through coal shortage or Administrator's orders.

ST. LOUIS, Jan. 23—St. Louis was not in 5-day suspension district and only one motor factory on the east side was affected. Men here strongly favored shutdown, as their business has been seriously affected by failuse to get supplies from the East.

MINNEAPOLIS, Jan. 24—General resumption of industries to-day. No such shortage of fuel here as in East, and Great Falls, Mont., to-day offered 2000 tons daily. Farm machinery for spring use now exempted and Fuel Administrator wired Washington to know if tractor plants are included.

CHICAGO, Jan. 24—Plants in this territory affected by Monday closing as follows: Stromberg, Elgin and Case closed; Root & Vandervoort closed, but has 80 per cent Government work; Nash, Velie, Nordyke & Marmon open on Government work; Parrett and Waukesha engine all open, former on tractors for spring deliveries, latter on Government work; Diamond T closed, but has Liberty truck orders; Findeisen & Kropf, indirect Government orders, closed; Old Reliable, closed; Wisconsin Motors, Government orders, open; National, closed, except departments on Government orders; Mitchell, Government truck plant open; Emerson-Brantingham, same as Parrett; Hayes Machinery Co., closed; Kissel open on Government work; Haynes closed, but just started on Government work that may exempt them; Four-Wheel-Drive shut down Friday, but resumed operations Monday on Government orders; Holt did not shut down because of Government work; Stutz, closed; Wheeler & Schebler, closed; Prest-O-Lite, open for Government work.

England Protests at Curtailment

Motor Trade Assn. Gives Reasons Why Handicaps Should be Removed by Government

LONDON, ENGLAND, Jan. 1—An additional protest against the enforced curtailment of the automobile industry in Great Britain has been made by the Motor Trade Association, which represents the motor industry in its entirety. The protest sets forth the various reasons why the industry should not be handicapped as it has been, and advances information as to the essential characteristic of the industry in war times. In this connection the protest states:

"The rich man to-day represents the smallest fraction of the total motoring class of England. The vast majority, even of private motorists, use their vehicles for other than purely pleasure purposes. Far and away the largest proportion of motor vehicles are directly or indirectly in use for business and utilitarian purposes. Most of these vehicles are of moderate or low price and power, purchased because they represented economy of transport for persons and for goods."

The protest goes on to show the present numerical comparison between automobiles owned in Great Britain and those owned in the United States, and says that while the population of the United States is only twice that of Great Britain, the number of automobiles employed is five times greater. It follows this up by stating that there is a potential motoring population of England which is equal to several times the quantity of automobiles available.

The protest expresses regret that the automobile industry in England never received the encouragement and fostering facilities that it did in America, and cites that "it should not have been beyond the wit even of statesmen of quite ordinary vision to secure and safeguard sources of fuel supply."

"We therefore suggest," the protest continues, "that the State in its own interest should take the earliest opportunity to reconsider its attitude toward motorists, motoring, and the motor industry.

"The motorists of the country, and the personnel of the motoring industry of the country have made sacrifices equal to any other section of the people. They have rendered that service gladly and thoroughly. They ask for no more reward, or recognition than may properly be claimed by any other body of citizens; but they ask for just that much.

"They protest against being taxed as motorists, after being taxed as citizens, because no other body of citizens is twice taxed in that way. They protest against being dealt with as pariahs, after having rendered special service. They protest against being the only body of road users required, as such, to bear the burden of

Digitized by Google

road making and maintenance. They protest against a tax on fuel for vehicles admittedly indispensible to national efficiency.

"The motor trade joins with motorists in all their protest, and adds its own against its plants being commandeered and diverted to other uses without guarantees for the future.

"Without losing sight of causes it emphasizes a fact, which is not at all sufficiently appreciated, namely, that through the complete turning off of supplies the motor trade has been destroyed literally by starvation.

"It protests against the efforts which are continually being made to represent motoring in any form, and for any purpose as nationally reprehensible, and the purchase of a serviceable motor vehicle as an unpatriotic act while purchase of expensive clothing, jewels, cigars, wine, and other less serviceable articles is encouraged."

The protest accuses the government of being directly responsible for the high price of gasoline, and declares that this is double the reasonable market price solely because of national neglect to secure adequate supplies.

Spranger Heads Wheel Company

DETROIT, Jan. 19—At the annual meeting of the Spranger Wire Wheel Corp. the following officers were elected: Dr. N. M. Spranger, president; Jacob M. Schaefer, vice-president; William Finzel, treasurer; John F. Reinke, secretary; John A. Lancaster, Frank Spranger, Christopher E. Stein, Fred R. Schmalzreidt and J. Robert Wilkin, directors. J. Robert Wilkin has been appointed sales manager; Albert J. Hall, assistant general manager; Ed. T. Walling, sales manager and director of purchases.

Light Truck Made by Collier Co.

Single ¾-Ton Model to Sell for $885—Fitted with 3 Types of Body

BELLEVUE, OHIO, Jan. 22—The Collier Motor Truck Co. is manufacturing a single truck model—a three-quarter-ton truck fitted with any one of three bodies and selling for $885. Features of this truck are light weight, flexibility and moderate price.

The Collier truck is assembled from standard units and is designed throughout for heavy duty. A 4-cylinder Lycoming engine with a 3¼-in. bore and a 5-in. stroke is used. Conforming with modern practice, the valve mechanism is entirely enclosed and automatically lubricated. The oil is circulated by a plunger pump and is of the positive feed type. Cooling is by a thermo-syphon, a Zig-Zag tube radiator being used.

Among the engine accessories are a Zenith carbureter and a Connecticut ignition system. The electrical system is particularly complete for truck practice, comprising an Auto-Lite starting and lighting system together with a Willard storage battery.

The gearbox and truck are a unit with the engine, a dry plate Raybestos on steel clutch being used together with a selective three-speed sliding gear set. The drive is taken through a propeller shaft fitted with two universals to the three-quarter floating Salisbury rear axle.

Both front and rear springs are semi-elliptic, the former being 37 in. and the latter 50 in. long. These are special electric furnace steel, and carried on hardened and ground spring bolts fitted with grease cups. The wheelbase of the truck is 118 in. and it is mounted on 32 by 4-in. pneumatic tires. The weight complete is 2600 lb.

As stated, 3 types of bodies are offered, each having a loading space of 7 ft. The first is completely enclosed, the second an open express with driver's cab, and the third is a completely roofed express body.

Industrial Review of the Week

A Summary of Major Developments in Other Fields

Little Effect on Steel Industry of Closing Order

With so large a part of their product, particularly in heavy lines, going to the Government or its Allies, or to plants having Government contracts, the iron and steel industries felt less than others the closing down order of the Fuel Administration. Fresh snows and intense cold combined to aggravate the freight blockades, as the order went into effect, and made more difficult any measure of its effects.

It is estimated that the five days ending Tuesday brought a curtailment of 10 to 15 per cent from the already restricted rate of recent weeks. Probably 70 per cent of the blast furnace, open-hearth steel and coke oven capacity was kept in operation, but all Bessemer plants were down, the Government not buying converter product, and only such rolling mills were run as had been engaged in producing for ships and shells, including plate mills and some structural and boiler tube mills.

Not only is there great perplexity owing to the new priorities in fuel, but some observers see the steel trade drifting into a state of helplessness that bodes no good even for some work considered important to the war. Exemptions from the closing order do not meet the case if fuel needed to keep iron and steel works going has been diverted to uses higher up on the preferred list.

There has been prompt and generally strict compliance with the Garfield order not only by producers but manufacturer-consumers of iron and steel. Blast furnaces were considered exempt, and open-hearth furnaces in many cases produced much more steel than would take care of exempted rolled product, the remainder going into stock ingots. Rolling mill operation was much curtailed.

The steel trade sees the bearing of the week's events on the effort at Washington to have steel production and prices put under the same executive control that now exists in food and fuel, opinion being that the chances of the Pomerene bill have not been helped by the results of centralized power over fuel.

As a result of the country's engrossment with the throwing of millions of workers into idleness the steel market has had fewer transactions than in months.

Some agricultural implement manufacturers have come into the market for early requirements in both soft and hard steel bars, on a scale pointing to large production in the coming season. In the automobile trade a rather more hopeful view is taken, some makers looking for about 50 per cent of their normal output.

Government awards are being made on 4400 cars for use in France.

A New Service

Herewith AUTOMOTIVE INDUSTRIES *supplies for the benefit of its readers a general summary of important developments in other fields of business. This is rendered possible by the editorial co-operation of leading industrial publications which are recognized authorities.*

By compressing the general industrial situation into this form we hope to give our readers a clear and comprehensive idea of up-to-the-minute developments which they could otherwise secure only with considerable expenditure of time and effort.

Some buyers of finished steel for commercial uses have found it easier to place contracts for plates, shapes, sheets and bars, and mills have been rather more inclined to accept export business on which permits have been obtainable.

Comment has been passed on the action of the Navy Department in seeking bids on various products included in the official price schedule, but not among the few on which prices were specifically announced by the President. It does not appear, however, that bidders are actually naming competitive prices in such cases.—*Iron Age.*

—

Weather Hampers Coal Distribution

A cold wave—the coldest for the season in many years—descended on the country, particularly the region west of the Allegheny Mountains during the week under review. The low temperatures were accompanied with high winds and in some localities heavy snows. This tied up railroad transportation to a considerable degree, and while causing an increased consumption, particularly of domestic fuel, rendered receipts much lighter than normal. The suffering in some localities was intense. Along the Atlantic seaboard in particular the movement of coal was considerably hampered by ice in the rivers and harbors. Baltimore, New York and Boston have been and are still suffering in no small degree from this cause, while Hampton Roads is not without its troubles of a similar nature. Of course, the cold weather exerted an adverse effect on production, and many mines worked only part time, and in many cases only partly manned because of the storm. Conditions in New England, while probably no better, or but slightly so, than a week or two ago, are probably no worse. The priority order granted this territory of 500 cars per day of bituminous coal is certain to have its effect sooner or later, but this effect can not be expected immediately. On the other hand, it is believed in some quarters that the diverting of this coal to New England will adversely affect industries in New York, Pennsylvania and some of the Eastern states, and considerable protest is heard concerning it. It would appear that domestic shortage has been in many instances considerably relieved. In some localities, however, added inconvenience and no small amount of suffering was caused by the severe weather conditions. The improvement in transportation, which was being shown in some of the coal producing districts was, of course, nullified by the cold wave. It is believed, however, that as soon as the weather moderates for any length of time the transportation tangle can be largely straightened out, and this will doubtless, at least in large measure, relieve the present stringency. The drastic rulings of the Fuel Administration concerning coalless days may also exert a more or less potent influence in this direction.—*Coal Age.*

20,000 Disteel Wheels for Government

DETROIT, Jan. 23—The Detroit Pressed Steel Co. will build 20,000 disteel wheels for the 1½-ton aviation trucks ordered by the government.

—

Rumney Made Lieutenant

WASHINGTON, Jan. 23—Mason P. Rumney, formerly sales manager of the Detroit Pressed Steel Products Co., Detroit, has received the commission of lieutenant in the ordnance department of the United States Army.

—

Olds Hampered by Freight Conditions

LANSING, Jan. 23—The Olds Motor Works has enough orders on hand to keep the plant running at capacity during the winter months, but due to the fact that deliveries cannot be made business has had to be held over until conditions improve. Oldsmobiles have been driven to Chicago, Toledo, Grand Rapids and Michigan City, where it is possible to get freight cars, and from these points have been shipped to their destination.

—

Paige Profits Over $1,000,000

DETROIT, Jan. 22—Profits of the Paige-Detroit Motor Car Co. for the fiscal year ending Dec. 31 amounted to over $1,000,000, according to a statement at the annual meeting of stockholders to-day. The following directors were re-elected: Harry M. Jewett, Edward P. Jewett, Walter B. Cady, Gilbert W. Lee, Charles B. Warren, Jerome P. Remick, E. D. Stair, Sherman L. Depew, all of Detroit, and George de B. Keim, of Philadelphia. The directors re-elected the officers as follows: Harry M. Jewett, president; Edward P. Jewett, vice-president; Walter B. Cady, secretary; Gilbert W. Lee, treasurer; F. L. Jewett, assistant to president and assistant treasurer.

Car Supply Worries Wisconsin

Dealers at Tenth Milwaukee Show Discuss Ways of Meeting Demand

MILWAUKEE, WIS., Jan. 19—This is the most momentous year in the history of the motor car trade of Wisconsin, as it is for the entire industry of the United States. With the best year on record behind them, Wisconsin distributers and dealers, gathering in intimate conferences at the tenth annual Milwaukee show, which is the yearly opportunity for frank and full discussion and interchange of ideas and opinions, seem to hold but one thought—Will we be able to obtain enough cars to fill our requirements? It is not a question of a market, or ability to sell that market, but a problem of furnishing enough stocks to supply its demands.

Business conditions similar to those which made 1917 Wisconsin's greatest motor year presage an equally great new year, or a greater one, so far as the number of prospective buyers of motor vehicles is concerned. The public purse still is well filled. The inclination to purchase motor cars is stronger than ever, in spite of advancing prices. It is a conservative statement to say that every motor vehicle that the manufacturers put into Wisconsin during 1918 will be eagerly absorbed and there will remain an aching void if the number offered is not greater than it was in 1917.

At this time the Wisconsin average is approximately one car to every 17 inhabitants, the population of the commonwealth being figured at 2,800,000. In 1916 the number of cars averaged one to every 24 inhabitants. This is not the best showing made by any State in the Union, but it indicates that the growth of the use of motor vehicles in Wisconsin is a healthy one, and selling is not being overdone by any means, with no possible likelihood of saturation of market.

Talks with leading distributers and dealers at the Milwaukee show serve to indicate that Wisconsin's record in 1917 represents an achievement. In the face of some of the greatest difficulties that the motor car trade has ever been obliged to meet, in excess of 10,000 cars were sold in Wisconsin than was predicted at the beginning of last year. The conditions under which distributers and dealers worked during the latter part of the period are too well known and understood to make explanation necessary. Yet the total business of practically every dealer showed a very appreciable gain over 1916.

Wisconsin Registration For Six Years

	1917	1916	1915	1914	1913	1912

22 More M. A. M. A. Firms for Chicago Show

NEW YORK, Jan. 19—The Motor & Accessory Manufacturers' Assn. has added the following concerns to the list of exhibitors at the Chicago Automobile Show:

Air Device Co.....Chicago
F. A. Ames Co.....Owensboro, Ky.
Anderson Forge & Machine Co.....Detroit
Auto Pedal Pump Sales Corp.
456 Fourth Avenue, New York
Bay State Pump Co.....Boston
Carburetor Mantle Co., Inc.
1476 Broadway, New York
Copeman Laboratories, Inc.....Flint, Mich.
G. L. W. Spring Oiler Co....San Diego, Cal.
Gibraltar Jack Co..1902 Broadway, New York
Guarantee Liquid Measure Co.
Pittsburgh, Pa.
McCord Mfg. Co.....Detroit
Menominee Electric Products Co.
1756 Broadway, New York
Miller Transmission Co.
90 West Street, New York
New Era Spring & Specialty Co.
Grand Rapids, Mich.
Wm. E. Pratt Mfg. Co.....Chicago
Rajah Auto Supply Co....Bloomfield, N. J.
Rand Mfg. Co.....Haverhill, Mass.
Rex Mfg. Co.....Connersville, Ind.
Taft-Pierce Mfg. Co.....Woonsocket, R. I.
C. R. Wilson Body Co.....Detroit
Wire Wheel Corp. of America..Buffalo, N. Y.
Woodworth Mfg. Co....Niagara Falls, N. Y.

Will Not Move Girl's Office

WASHINGTON, D. C., Jan. 21—The plans for moving the offices of Christian Girl and the Military Truck Production Board to the Union Depot Office Building has been abandoned. Mr. Girl and his organization will remain at 1421 Eye Street. J. G. Utz, supervisor of inspection and engineering of the board, has removed his offices, however, from Mr. Girl's division to the Union depot. The Military Truck Production Board which, as was recently stated in these columns, now includes the functions of engineering and maintenance as well as production of Liberty trucks, is now known as the Motor Transport Section of the office of the Quartermaster General. This entire section is headed by Mr. Girl as chairman.

French Becomes a Lieutenant

INDIANAPOLIS, Jan. 22 — Lucius French, advertising manager of the National Motor Car & Vehicle Corp., Indianapolis, has resigned to accept a commission of first lieutenant in the United States Ordnance Department. He will be attached to the motor equipment section.

Australia Modifies Import Law

Extends Time for Shipment of Detached Bodies from U. S. Until March 31

NEW YORK, Jan. 23—The Australian government has made an additional ruling with regard to the shipment of automobile bodies from America to Australia and which ruling extends for a period of 3 months the time in which bodies can be shipped from America to Australia without being fitted on their chassis or accompanied by additional chassis.

The new ruling states that bodies may be shipped from America up to March 31, 1918, which is really a 3 months' extension. This information, given out by the Australian Department of Trades and Customs in this city is really the fourth step in the program with regard to prohibition of automobile bodies which started on Aug. 10.

Prohibition Proved Embarrassing

The absolute prohibition placed on the importation of bodies into Australia at that time proved embarrassing because body builders in Australia were not able to cope with the requirements and a famine of bodies was precipitated.

The ruling was modified so that a complete car was admitted, providing two additional chassis were imported at the same time. Now the final ruling extends the period of receiving bodies without any restrictions whatever, providing they are shipped from America prior to March 31.

Double Aviation Appropriation

WASHINGTON, D. C., Jan. 21—Major-General George O. Squier of the Signal Corps and member of the Aircraft Production Board is asking Congress today for $1,032,294,260. This amount almost doubles the $640,000,000 already allotted for the Aviation program, and does not include $105,000,000 additional which is estimated for the needs of the Signal Corps.

Secret Progress Report

General Squier explained behind closed doors the progress already accomplished and gave the figures and technical details showing what it is expected this billion dollars asked for will accomplish. The Aircraft Board operating on a very efficient basis eliminates all red tape in its methods. It is spending an average of $2,000,000 a day and no contractor has ever to wait more than twenty-four hours for payment. Plans conceived in the morning are voted on at noon and put into operation before night. The need for the billion dollars is created by the fact that the money already allotted has for the most part already been converted into fighting material and into the accessories needed for the conquest of the air.

Men of the Industry

Changes in Personnel and Position

C. S. Thompson Joins Four-Wheel-Drive Co.

CLINTONVILLE, WIS., Jan. 21—C. S. Thompson, Chicago, has been appointed manager of foreign sales of the Four Wheel Drive Automobile Co., Clintonville, Wis., to fill the vacancy caused by the resignation of J. M. Homs, who has become associated with his brother in the exporting business in New York City.

—

H. G. Ault has been named by the General Tire & Rubber Co., Akron, to head its reorganized sales department covering tire accessories and repair materials. Ault has been connected in a similar capacity with the Firestone Tire & Rubber Co.

—

C. W. Whitston has joined the sales force of the Fulton Motor Truck Co., with headquarters in Chicago. Immediately after the Chicago show he will be assigned the position of district sales manager.

—

E. G. Hosler, formerly connected with the Willys-Overland Co., Toledo, as district manager of the mid-western division, has purchased the Overland-Houston Co., Houston, and on Jan. 1 assumed the duties of president and general manager.

—

Harry Cunningham has become associated with the engineering staff of the Maxwell Motor Co., in the war truck department. He was formerly head of the Cunningham Auto Sales Co., Michigan Maxwell distributer, and has passed examination for a major's commission in the non-flying section of the Aviation Corps.

—

W. J. Drumpelman has been appointed assistant sales manager of the Hudson Motor Car Co., Detroit. He was formerly assistant general manager of the Elgin Motor Car Corp., and has been in the sales department of the Lozier, Oldsmobile and Chalmers companies.

—

Frank J. Foley, formerly manager of the mining department of the Westinghouse & Electric Mfg. Co., has become associated with the Edison Storage Battery Co., Orange, N. J. He will manage the mining and traction department, with headquarters in Orange.

—

Morton P. Leihy, branch manager of the Locomobile Co. of Missouri has been appointed branch manager of the Nordyke & Marmon Co., Kansas City, to succeed Major A. L. Ellwood, resigned to enter the army service as aviator.

—

C. Floyd Greene has been appointed wholesale director of the E. A. Myers Co., Pittsburgh. He was formerly district manager of the Chalmers Motor Co.

—

Nelson Hall has been appointed production engineer of the Fisher Electrical Works, Detroit, manufacturers of electrical starters for Ford cars.

—

Franklin T. Chapman, formerly body engineer and assistant to the manager of the Olympian Motors Co., has been appointed assistant general sales manager of E. F. Houghton & Co., Pontiac.

—

D. H. Wetzel, for the last 5 years sales manager of the Mott Wheel Works, Jackson, Mich., has resigned.

—

Charles A. Swan, formerly superintendent of the Becker Steel Co. of America, has joined the sales organization of the Hess Steel Corp., Baltimore. He will represent the Hess company in Cleveland and Detroit territory.

—

W. H. Knowles, who was formerly chief engineer of the Saxon Motor Car Co., has been appointed superintendent of Hale & Kilburn Co., Philadelphia.

—

Shope Made Zenith Sales Manager

DETROIT, Jan. 21—V. I. Shope has been appointed sales and advertising manager of the Zenith Carburetor Co., to succeed A. H. Doolittle, who resigned recently. Shope was formerly New York branch manager of the company.

—

DIVIDENDS DECLARED

The Fisher Body Corp. has declared a regular quarterly dividend of 1¾ per cent on the preferred stock, payable Feb. 1 to stock of record Jan. 21.

The Westinghouse Electric & Mfg. Co. has declared the regular quarterly dividend of 1¾ per cent, (87½ cents per share) on the common stock, payable Jan. 31 to stock of record Dec. 31.

The Stewart-Warner Speedometer Corp. has declared the usual quarterly dividend of 1½ per cent on the common stock, payable Feb. 25. Books close Jan. 30 to Feb. 20, inclusive.

A quarterly dividend of $1.25 a share has been declared on the common stock of the Pierce-Arrow Motor Car Co., payable Feb. 1 to stock of record Jan. 17.

The Kelsey Wheel Co. has declared a preferred quarterly dividend of $1.75 payable Feb. 1 to stockholders of record Jan. 21.

The Nash Motors Co. has declared a regular quarterly dividend of $1.75 a share on the preferred stock and an initial dividend of $6 a share on the common stock, payable Feb. 1 to stockholders of record Jan. 19.

The Curtiss Aeroplane & Motors Corp. has declared a semi-annual dividend of 3½ per cent on preferred stock, payable Jan. 15 to stock of record Jan. 2.

New Companies Formed

Latest additions to ranks of Automotive Industries

Star Co. to Make $750 One-Man Tractor

FINDLAY, OHIO, Jan. 21—The Star Tractor Co. has begun the erection of several buildings in which to construct the Star tractor, a $750 one-man machine. The company has been organized with a capital stock of $100,000, with some of Findlay's best known financiers. J. E. Bicknell is president of the corporation; C. A. Schubert, vice-president; C. E. Jordan, secretary; C. L. Casterline, trustee, and F. H. Gerdemann, engineer.

—

BARABOO, WIS., Jan. 21—A. S. Lanich, who recently disposed of his garage and retail business, one of the first to be established in Baraboo, Wis., will engage in the manufacture of a line of garage specialties of his own invention, which he has been producing on a small scale for a year or more. The principal article will be an automatic opening and closing device for garage doors, which also is suitable for double-doors of shipping rooms, factories, etc. Several are now in operation in large Wisconsin garages. For the present contracts for casting and machining the parts will be made with commercial foundries until the business assumes sufficient size to make possible the establishment of a complete plant in Baraboo.

—

MILWAUKEE, Jan. 21—The Texas Co., Houston, Tex., producer and refiner of petroleum products, has been granted a charter in Wisconsin and will open a branch in Milwaukee. The capital stock is $5,500,000 and the Wisconsin interest is given at $5,000.

—

Chevrolet General Offices in New York

NEW YORK, Jan. 19—The Chevrolet Motor Co. has moved its general offices from Flint, Mich., to Broadway and Fifty-seventh Street, New York. The New York store will be located in the same building.

—

Government Work for Haynes

KOKOMO, Jan. 18—The Haynes Automobile Co. expects a Government contract for the manufacture of 4000 motors and 4000 transmissions, entailing a cost of about $3,000,000. These orders would keep the company's plant in capacity operation for 6 months, and the production of pleasure cars probably would be curtailed temporarily, according to representatives of the company.

Current News of Factories

Notes of New Plants—Old Ones Enlarged

Detroit Shell Buys Springfield Body Plant

DETROIT, Jan. 22—The Detroit Shell Co. has purchased most of the assets of the Springfield Body Co., including buildings, land and all machinery except that used for wood working. The sale, which brought $600,000, does not include stock on hand, accounts in receiving or patents. The sale of patents on the Springfield body is pending, and patent litigation with the Fisher Body Corp., Detroit, has been successfully terminated. Barney F. Everett, trustee of the bankrupt company, states that the general creditors will doubtless receive 75 cents on the dollar. The Detroit Shell Co. is contemplating important additions to the Springfield plant.

Hayes Wheel to Start Production

JACKSON, MICH., Jan. 21—C. B. Hayes has been elected president of the Hayes Wheel Co. The plants of the Jackson Automobile Co. and the Mutual Motors Co. here will be utilized and the company hopes to start production before the middle of February.

Case Tractors for France

RACINE, WIS., Jan. 21—The J. I. Case Threshing Machine Co., Racine, Wis., has received an order from the French Government for 2000 gas-oil tractors with three-bottom plows, and began deliveries during the week. The 2000 machines are of the 10-20 type. A large number of tractors of a heavier and more powerful type also will be built for France. The Case company recently shipped a large order of tractors and separators to Italy.

May Sell Metz Plant

WALTHAM, Jan. 19—The Metz Co. is planning to sell its plant to liquidate its debts. It will retain one part of the group of buildings in which it will carry on Government work. The matter has been under consideration for some time and a decision was reached a few days ago. The company has some 40 acres of very valuable land, and a lot of fine machinery which should bring good prices now with the demand for these things due to war work in New England.

Overland Starts Airplane Work in Elmira

ELMIRA, N. Y., Jan. 21—The Willys-Overland Co. is manufacturing patterns, dies and jigs, and is assembling airplane engines in its plant here. In its Elyria, Ohio, plant, connecting rods, crankshafts and miscellaneous parts are being made.

National Wheels for Fisher Body Corp.

GENEVA, N. Y., Jan. 21—The National Wire Wheel Works, Inc., will furnish the new type Palmer airplane wheel to the Fisher Body Corp., Detroit. This wheel has been adopted by the Government for use on heavy airplanes.

American Forging Quadruples Output

PONTIAC, MICH., Jan. 21—The American Forging & Socket Co. has quadrupled its output in the last 2 years. The socket department has increased its capacity to 1000 sets a day and employs 150 men.

Olson Truck Going Overland

DETROIT, Jan. 22—In spite of the inclement weather, the Swedish Crucible Steel Co. started one of its Olson 2-ton truck units overland for New York. Two and one-half days were required to reach Cleveland. A full load is being carried.

$20,000,000 Contract for Weidely Motors Co.

INDIANAPOLIS, Jan. 21—The contract of the Weidely Motors Co. for the manufacture of $3,000,000 worth of tractor engines for the Cleveland Tractor Co., Cleveland, has been increased to an order of $20,000,000. To meet the increased expense the Weidley company has issued $400,000 in additional preferred stock, making the total amount $500,000. The company expects to construct new buildings at a cost of $150,000. The program calls for 15,000 motors in 1918, 25,000 in 1919 and 30,000 in 1920. The present output is from 15 to 20 daily.

Marmon Enlarging Plant

INDIANAPOLIS, Jan. 21—The Nordyke & Marmon Co. is completing plans for enlarging its plant. Approximately $400,000 will be expended for the new building and $1,500,000 in machinery. The company is working on a government contract for airplane engines.

New Clubhouse of the Engineers' Club of Dayton

(*Continued from page* 223)

lantern booth. This booth is entirely concealed at the rear of the auditorium and is provided with all modern appliances and conveniences.

Four fireproof stairways lead from the auditorium to the ground level which, together with a fireproof building offer the best possible protection to the occupants.

On the third floor are two attractive bedrooms, cheerfully decorated and furnished, which have bath and toilet facilities conveniently located.

A suburban locker room is also provided on this floor for the convenience of those members living some distance from the club building. The whole building is provided with large steel casement windows, affording ample light at all times.

Fuel for Automotive Apparatus

(*Continued from page* 228)

The utilizing in automobile engines of a type of fuel that contains the combined gasoline and kerosene fractions of crude petroleum would certainly double the available supply, and even if all the other agencies working to this end failed the automotive engineers themselves would postpone for a long time the fateful day when their industry will be handicapped by not having available the material to feed engines after they have been produced.

Author's Conclusion

The present paper has developed along rather heterogeneous lines but can be summarized rather simply. The present fuel situation, in spite of the fact that gasoline is high in price and relatively low in volatility, is good. This will be appreciated more fully if war conditions add one more inconvenience to the already lengthy list that the country is experiencing. The newer types of gasolines are not inherently worse than the old; the price is not out of proportion to the price of crude petroleum, and the supply is abundant and well distributed.

In the future it appears that oil producers must secure more crude petroleum and refiners must get greater yields of volatile products out of oil treated. Designers must work toward higher standards of fuel economy and must strive to develop engines that will handle fuels of lower average volatility than the present type. A certain increase in supply of fuel may be counted on from the coal distillation industry and eventually the supply may be derived either from oil shale or from fermentation industries.

In closing it is desired to remind the members of the Society of Automotive Engineers that the present paper makes no pretense of being a last word on the important subject with which it deals.

The various phases of the fuel situation could be discussed at almost infinite length, and it is realized that even the few problems mentioned in this paper have not been given the detailed consideration they deserve. It is hoped, however, that the attention of the engineers of the Society may have been called to some other problems that they can profitably study.

New Process May Triple Gasoline

NEW YORK, Jan. 21—A new process, which, it is stated, will triple the quantity of gasoline obtainable from crude oil, is said to have been perfected by Dr. A. H. Ramage, who is a member of the American Electro-Chemical Society. It is stated that a company has been formed in Detroit to manufacture and market gasolene produced under this new process, and that Christian Girl, head of the Standard Parts Co., Cleveland, is interested in the company, which also includes A. H. Goss, a Detroit capitalist; E. W. Farr, a Cleveland capitalist; S. A. Fletcher, an Indianapolis banker; H. B. Smith, a Bay City, Mich., banker; F. C. Finkenstaedt, Bay City, formerly head of the National Cycle Co.; H. B. Barhart, head of the White Star Oil Co., Detroit, and A. E. Leopold, a Chicago capitalist. It is stated that the process differs from the Burton process and does not employ the cracking principle. Instead the oil is claimed to be chemically charged as it passes through the stills with the result that the yield of gasolene is tripled. It is said that the owners of the process have offered it to the Government.

Gillette Tires for New York Cars

EAU CLAIRE, WIS., Jan. 21—The Gillette Rubber Co. has been awarded the contract for furnishing the city of New York with all pneumatic tires required for municipally-owned vehicles during 1918. The plant has now reached a daily production of 350 casings and 400 tubes and the output is being increased as rapidly as possible. Reclaimed and waste material is being worked up into rubber heels and other commercial rubber goods, for which the company has gained an outlet for its entire production for some time ahead.

Calendar

ASSOCIATIONS

Feb. 4-7 — St. Louis, American Road Builders' Assn. Convention.

April 18-20 — Cincinnati, Fifth National Foreign Trade Convention.

GENERAL

Jan. 22-24—Montreal, Can., Convention of All Men Interested in the Automobile Industry in Eastern Canada.

Jan. 29-31—Chicago, Annual Convention, Garage Owners' Assn. of Ill., Green Room, Congress Hotel.

SHOWS

Jan. 16-25 — Milwaukee, Wis., Milwaukee Automobile Dealers, Inc., Auditorium. (First 7 days, passenger cars; last 3 days, commercial cars.) Bart J. Huddle, Mgr.

Jan. 18-24 — Des Moines, Ia., Ninth Annual Passenger Car and Second Annual Truck, Des Moines Automobile Dealers' Assn., Coliseum. C. G. Van Vliet and Dean Schooler, Mgrs.

Jan. 19-26—Detroit Automobile Dealers' Assn., Overland Bldg. H. H. Shuart, Mgr.

Jan. 19-26 — New York Motor Boat Show, Grand Central Palace, National Assn. of Engine and Boat Manufacturers.

Jan. 19-27 — Cleveland, Seventeenth Annual. Cleveland Automobile Show Co., Wigmore Coliseum. Fred. H. Caley, Mgr.

Jan. 19-26 — Montreal, Can., Montreal Automobile Trade Assn., Ltd., Almy Bldg. T. C. Kirby, Mgr.

Jan. 21-26—Scranton, Pa., Scranton Motor Trades Assn., Armory. Hugh B Andrews, Mgr.

Jan. 21-26 — Wilmington, Del., Hotel Du Pont.

Jan. 21-26—Buffalo, N. Y., Buffalo Automobile Dealers' Assn., Broadway Auditorium.

Jan. 21-26—Richmond, Va., Richmond Automobile Dealers' Association, First Regimental Armory Henry B. Marks, Mgr.

Jan. 22-26 — Mifflintown, Pa., Automobile Trade Assn. Valley Stream Auditorium.

Jan. 22-26—Baltimore, Md., Baltimore Automobile Dealers' Assn. and Automobile Club of Maryland, 5th Regiment Armory.

Jan. 22-26 — Oklahoma City, Okla., Oklahoma City Automobile Dealers' Assn., 701 No. Broadway. Roy H. Haun, Mgr.

Jan. 23-28—Allentown, Pa., Lehigh Auto Trade Assn., Traylor Motor Co.'s Garage. P. W. Leisering. Publicity Mgr.

Jan. 26-Feb. 2 — Chicago National Show, Coliseum and Armory, National Automobile Chamber of Commerce.

Jan. 26-Feb. 2—Chicago, Salon, Elizabethan Room of Congress Hotel.

"There doubtless are other good bearing bronzes, but I *know* Non-Gran is good and I *know* Non-Gran is uniform."

The man and engineer who spoke those words is known to every Automotive Engineer not only of this Country but of the entire World. You know him, as does everyone else, as easily one of the first five Automotive Engineers of America. In those few words hasn't this man expressed the majority opinion of the entire American Automotive Industry?

JOHNSON'S RADIATOR CEMENT

Repairs Leaky Radiators Instantly

Stop Those Leaks

THE easiest and quickest way of repairing leaks in radiators, pumps, water jackets, hose connections, etc., is to use Johnson's Radiator Cement. This will stop the leaks in just a few minutes without laying up the car. No mechanical experience is required—all you have to do is to remove the cap and pour the cement into the radiator.

JOHNSON'S RADIATOR CEMENT

Johnson's Radiator Cement blends perfectly with the water until it reaches the leaks—just as soon as it comes in contact with the air it forms a hard, tough, pressure-resisting substance which is insoluble in water and consequently makes a permanent seal.

Quick—Efficient—Harmless

Johnson's Radiator Cement contains nothing which can clog or coat the cooling system. It will ordinarily seal leaks in from two to ten minutes. It requires no experience to use Johnson's Radiator Cement.—All you have to do is to remove the radiator cap and pour it in.

Quarts, $1.75 Pints, $1.00 Half-pints, $ .65

JOHNSON'S PREPARED WAX

Liquid and Paste

Keeps Your Car Young -

FOR POLISHING, preserving and protecting the finish of motor cars, no polish can take the place of Johnson's Prepared Wax (Liquid or Paste). Johnson's Prepared Wax is accepted standard the world over. More is used than all other polishes combined.

Johnson's *Liquid* Prepared Wax is a revelation to motorists who prefer a liquid polish. It polishes immediately with but very little rubbing. You can go over a good sized car in half an hour.

Johnson's Prepared Wax covers up mars and scratches—prevents checking and cracking—sheds water and dust—removes road-oil—and makes a "wash" last twice as long.

JOHNSON'S CLEANER

Johnson's Cleaner entirely removes all stains, discolorations, scum, tar, grease, etc. Even those spots that are ground in—mud freckles—and surface scratches which you thought were permanent—will disappear like magic under Johnson's Cleaner. It doesn't injure or scratch the finest varnish—simply cleans and prepares it for the Johnson's Prepared Wax polish.

If you cannot get Johnson's Cleaner and Johnson's Prepared Wax of your dealer, order direct from us, and we will prepay the express to any point in the U. S. East of the Rockies.

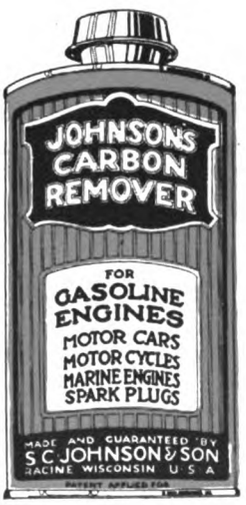
JOHNSON'S CARBON REMOVER

Keeps Your Motor Powerful

YOU KNOW that more than anything else you would prefer to have your car powerful and smooth-running. Carbon kills power—quick pick-up and hill climbing ability.



JOHNSON'S CARBON REMOVER

Johnson's Carbon Remover increases power—improves acceleration, stops that knock, quiets your motor—saves your batteries—and reduces your gasoline consumption 12% to 25%.

Positively Harmless

Johnson's Carbon Remover is a harmless liquid to be poured into the cylinders. It softens the carbon and releases it from the metal. It then burns, powders and goes out with the exhaust. Five minutes' time and no labor required. You will save from $3.00 to $5.00 over any other method, without laying up your car and with very much better results.

Use It Every 1,000 Miles

If you will use Johnson's Guaranteed Carbon Remover at regular intervals giving Carbon no chance to accumulate, you will automatically eliminate most valve trouble and your engine will always be clean. It will run as it did the first 500 miles—quietly and full of "pep."

Quarts, $1.75 Pints, $1.00 Half-pints, 65c

JOHNSON'S STOP SQUEAK OIL

Makes Your Car Ride Easier

IT keeps your springs—which are the natural shock absorbers of your car—permanently flexible and resilient. Apply it occasionally and your springs will retain their original easy riding qualities **indefinitely.**

Reduces Chance of Spring Breakage

Johnson's Stop-Squeak Oil prevents rust—stops squeaking. Rusty, squeaky springs break first. Friction causes them to crystallize. Squeaks warn you of friction and call for an immediate application of Stop-Squeak Oil.

No Trouble to Apply

You paint Stop-Squeak Oil on with a brush or squirt it on with an oil can. It instantly seeps between the spring leaves. No tools are required. You do not have to jack up the car, remove the spring clips or pry the spring leaves apart.

Stops Squeaks Anywhere About the Car

Johnson's Stop-Squeak Oil removes squeaks of any kind—in springs, shackle-bolts, bodies, windshields, fenders, tops, enclosed bodies. Just locate the squeak and touch it with the oil. It stops instantly.

Quarts..... .85 **Pints**..... .50

Order of your dealer or if he cannot supply you, order direct and we will prepay express charges to any point in the U. S. A. East of the Rockies.

JOHNSON'S FREEZE-PROOF

Prevents Your Radiator *from* Freezing

THERE is only one SURE way to prevent your radiator freezing. That way is to use a non-evaporating anti-freeze preparation. You cannot depend on alcohol or any other product which evaporates with water.

Does not Evaporate or Steam

Johnson's Freeze-Proof does not evaporate or steam. One application lasts all winter under normal conditions—making it the most economical anti-freeze compound on the market.

Cheaper and Better than Alcohol

Anyone can use it—simply dissolve in water and pour into radiator. One package will protect a Ford to 5° below zero. Two packages will protect a larger car to 5° below zero, and three packages to 20° below zero.

Absolutely Harmless

It does not injure rubber, cloth, packing or metal of any kind. It does not rust or corrode metal. There is less rust with it than with water alone or with water and alcohol.

Raises Boiling Point of Water

It not only prevents frozen radiators. It prevents overheating as well. It raises the boiling point of water (212°) anywhere from 225° to 250°, depending upon the amount of Freeze-Proof used.

Johnson's Freeze-Proof can be obtained from good dealers and supply houses in 6½ pound containers at $1.50 per package. If your dealer will not supply you send us his name and order direct.

This Book FREE Tells How to Keep Your Car Young

Write for This Book—It's Free

IT ISN'T FAIR to yourself or your car to run it two or three years without attention and then sell it at a big loss. With but very little effort you, yourself, can keep your car in such condition that the depreciation will be very slight. We manufacture a line of automobile products particularly for this purpose. No experience is necessary for the use of them—they can all be applied by the novice with perfect satisfaction.

Our booklet "Keep Your Car Young" tells how you can reduce automobile depreciation and on a turn-in or sale secure from 10% to 25% more for your old car. It will also tell you how to secure the maximum in pleasure and performance from the car you intend to drive next season—whether it is old or new.

Easy to Use

ALL OF JOHNSON'S Automobile products are very easy to use.—It requires no mechanical experience and but very little time. Write for it today. Insist upon your dealer supplying you with Johnson's Auto Products. Under no circumstances accept substitutes. Johnson's Line consists of the following:

Johnson's Prepared Wax—(liquid and paste)—the best polish for automobile bodies, hoods and fenders.—Sheds water and dust and makes a "wash" last twice as long.

Johnson's Cleaner — for removing spots, stains, discolorations, etc., and putting the finish in perfect condition for the wax polish.

Johnson's Carbon Remover cures 80% of engine trouble. Makes your car run like it did the first 500 miles. —No mechanical experience necessary.

Johnson's Stop - Squeak Oil — lubricates the springs perfectly. Removes squeaks from all parts of the car. Easy to use.

Johnson's Black-Lac — for dusty, grimy, gray tops, side curtains, cushions, etc. Does not rub off on the hands and clothing. Dries in fifteen minutes, ready to use.

Johnson's Auto-Lak — a body varnish that amateurs can use successfully. Dries in 24 hours.

Johnson's Freeze-Proof —prevents frozen radiators. One application lasts all winter.

Johnson's Radiator Cement (liquid)—our new product for 1918—of the same high quality as other ***Johnson*** preparations.

MARMON 34

Marmon Dominance

Today, And In The Days To Come

WHEN, in any industry, the law of diminishing returns sets in by whatever reason, the real leader quickly emerges from the rest. As for the automobile field, you have seen the Marmon pass through the back-fire of wartime, unscathed. Every day you meet this car in greater numbers in the motor traffic of America, overtaking, as it has, everything except demand.

Meanwhile, the Marmon has added more vital discoveries to the lore of motor car construction than any other car of the past decade.

And so, when peace shall at length remove the physical limitations to Marmon production and distribution, you may safely expect to see this car wield the influence overseas that it exerts at home.

On the following page—a few of the reasons why.

136-Inch Wheelbase—1100 Pounds Lighter

Chicago Automobile Show
Coliseum

Digitized by Google

MARMON 34

Advanced Engineering

THE car through which the world has received the much-wanted combinations not thought feasible prior to this car's introduction—a half-ton lighter weight, yet unexcelled roadability and riding ease; long wheelbase, yet short turning radius; deep, wide seats, yet exceptionally low body; great speed and power, yet small fuel and tire consumption.

And as for the dealers, the Marmon has given them ideal combinations too—higher average sales with lower sales expense; more gross business with less cost for service; an expanded fine car market with a permanent future.

Marmon sales records in small towns, small cities, and metropolitan centers, substantiate these facts. They are open to the inspection of interested dealers.

$6 for the best Jack in the World

Peteler AUTO JACK

TWO SIZES
8½" high-5½" lift
10½" high - 7" lift

The previous model of the Peteler Jack was considered the best, and it had a tremendous sale—but this model, the new Peteler Jack, is better—and better by a big, wide margin than any other jack ever built.

Consider its utility—there is a long telescoping handle which, together with the jack, occupies very little room in the tool box.

By means of the long handle it can be shoved to any point under the car, the car raised, then lowered and the jack withdrawn—all with the operator standing upright.

It has a short stroke so that the overhang of the car in any case cannot interfere with the up and down movement of the handle.

The lifting action is easy and quick—it goes up ⅜" to the stroke, which is far faster than other jacks.

There is no danger point—it raises to the limit of the length of the lifting bar without possibility of failure.

It lowers with the same facility—a turn of the handle operates a lever which reverses the action and—the car comes down step by step as it went up. When relieved of the load, and only then, a slight lift of the handle lets the lifting bar drop the remaining distance into the jack.

For right-off-the-bat utility, can you conceive of a better jack?

Digitized by Google

Manufacturing Corporation

Now then—

You dealers could sell the Peteler Auto Jack on appearance alone if you wanted to—for it's the most distinctive appearing, best proportioned, finest finished, staunchest looking jack you ever saw.

But add to that its world-beating utility, its surpassing power, its strength and endurance and you have a proposition full of possibilities for profit—because its features make the Peteler Jack easily salable to the great majority of the car owners of your locality.

The Peteler Auto Jack is almost as simple as your pocket knife. There's nothing complicated in its makeup—just a few working parts made of the finest materials for their purpose. A lifting bar of cold rolled high carbon steel, pawls of tool steel, plates of pressed steel and case of malleable iron—all fool proof and trouble proof and capable of a lifetime of wear.

The Peteler Jack has a capacity of 3000 lbs., 1000 lbs. more than it could possibly be called upon to lift—a half ton of over-strength. Furthermore, it is a non-skid jack—under any condition of load or road it can't slip.

In every respect the Peteler Jack justifies its title—"The Best Jack in the World"—and as such it should be on your counter, on your shelf, in your window. The price, $6, allows you a mighty liberal profit.

Sold through jobbers only

Make your pistons gas tight

The MUNGER "ALWAYS TIGHT" PISTON RING OUTFIT—

for FORDS
8 "Always Tight" Rings (Regular Size)
4 "Always Tight" Rings (Over Size)
1 Regrooving Tool
1 Ring Insertion Tool

Ready to insert the Munger Re-grooving Tool to true-up a worn piston groove

The Munger Re-grooving Tool in position for cutting. Testing width of groove with an over-size ring

A Munger "Always Tight" Piston Ring being slipped over the Munger Ring Insertion Tool

Showing how easily Munger "Always Tight" Piston Rings can be placed in the piston grooves with the Munger Ring Insertion Tool

MUNGER "Always Tight" Piston Rings

The MUNGER ALWAYS TIGHT EXPANSION JOINT

When piston grooves become slightly worn it is impossible to fit any rings in them gas-tight without first truing-up the grooves. With each complete set of Munger "Always Tight" Piston Rings is one oversize ring for each piston (to be used in worn grooves) and a Munger Regrooving Tool with which worn grooves can be straightened quickly and accurately without resorting to expensive lathe work, and without even disconnecting the piston from the connecting rod.

Munger Piston Rings *always* remain compression-tight.

These unique rings quickly conform to the shape of any cylinder and retain their perfect fit until completely worn out.

The wonderful compression-holding power of these simple one-piece rings is due to their scientific design and their accuracy of manufacture. The Munger Expansion Joint, so simple, yet so efficient—the patented process of peening, which makes these rings fit the walls of any cylinder—the minute oil grooves, which cause these rings to seat themselves almost immediately—are distinctive features that make Munger "Always Tight" Piston Rings superior to all others.

They are the easiest of all rings to install. With the Munger Ring Insertion Tool even a novice can place them in the piston grooves without breakage or the slightest trouble. And Munger Rings are the most inexpensive because they are practically wear-proof.

List price for all sizes up to 3¼ in. diameter, $1.25 per ring. With each complete set of rings a *Munger Piston Regrooving Tool* and a *Munger Ring Insertion Tool* are supplied without extra charge.

Know Harrison Radiators for Their Selling Value

If the cars you handle are equipped with Harrison Radiators you have a talking point that will help you sell them.

Show your prospects how Harrison construction, although the lightest per cubic inch, nevertheless has such "inbuilt" strength that a leakage from a frozen core is practically unknown.

Tell them the Harrison cooling system embodies greater fuel economy due to higher cooling efficiency.

Point out the big, free Harrison Hexagon air passages and explain why they promote cool, easy-flowing water circulation.

Tell them that Harrison lightness of weight, Harrison durability and other Harrison qualities are direct results of the peculiar arrangement and construction of the Hexagon cells, original with Harrison.

The list of Harrison users is another advantage to you. This representative list of cars, itself, adds prestige. Don't overlook the value of the name Harrison to you in making sales.

See Special Exhibit New York and Chicago Shows.

Point for Point There is no better Truck Axle built than Sheldon

1 THE SHELDON WORM-GEAR AXLE is encased in a *one-piece* housing. This means that instead of the various parts being cast separately and then welded together, the complete housing is cast in one mould. By virtue of this one-piece construction, there can be no loosening of parts, regardless of road or operating conditions—an extremely vital factor to consider where commercial haulage is concerned.

The one-piece axle housing furthermore protects and strengthens the working parts in a manner that cannot be duplicated in any other form of construction.

It requires from 90 to 100 tons hydraulic pressure to bend the housing double; even then it does not crack, owing to the extreme toughness of the metal used—the result of careful and expert annealing.

2 THE STRAIGHT OR DAVID BROWN TYPE OF WORM is used in the Sheldon Axle because it has proved to be more silent and more double, as well as the simpler of the two types of worm generally in use. Neither use nor abuse can make it noisy. Forged from the finest steel, and heat-treated to wear-proof toughness, the worm threads are machined to microscopic limits.

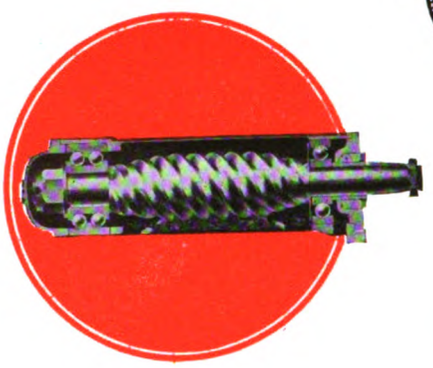
The worm carrier, in which the worm is mounted, is a substantial casting, machined so accurately that later adjustment is never necessary.

The lower section of the worm wheel runs in a bath of oil in the base of the housing. This is splashed through the worm shaft bearings, maintaining a constant film of oil between the surfaces of the worm threads and the teeth of the worm gear.

3 SHELDON BRAKES, are made ultra-efficient, to insure complete safety of operation. This is accomplished by means of double external expanding type of brake—simple in operation, self intensifying, easily adjusted, exceedingly powerful, quick-acting and unfailingly sure.

Sheldon brakes have a generous bearing surface and are doubly enclosed to thoroughly protect the bearing surfaces from dirt, grit and other foreign substances. The brakes are easily accessible for relining. When it comes to the question of adjustment, it is not necessary to touch the brakes themselves; they are tightened merely by moving back the sector to which the brake pull lever is bolted, and inserting the lever bolt in the next hole.

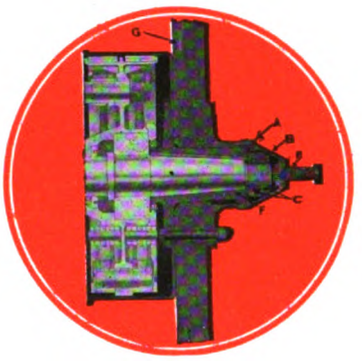
4 SHELDON AXLES are of the semi-floating wheel bearing type. Consequently Sheldon axles are more simply constructed by reason of fewer parts, lighter in weight for the same reason, yet have a greater carrying capacity than the full-floating type. This simplified construction means greater accessibility and the greater carrying capacity means greater economy of upkeep and operation.



The wheels in the Sheldon axle are mounted on an extra heavy axle shaft which bears the dead load of the truck. In the full-floating type the wheels are mounted directly on the less dependable tubular extension of the axle housing—a construction in which any slight bending, as a result of skidding or other causes, requires an expensive replacement—generally a factory repaid job.

But the greatest advantage of Sheldon semi-floating construction is graphically shown in the sketch opposite. To the left (Fig. 1) is illustrated the simple leverage angle of the full-floating type against the side strains at the wheel rim, and to the right (Fig. 2) is shown the wide leverage angle of the Sheldon semi-floating construction. Obviously the latter incorporates the correct principle for resisting side strain.

Digitized by Google

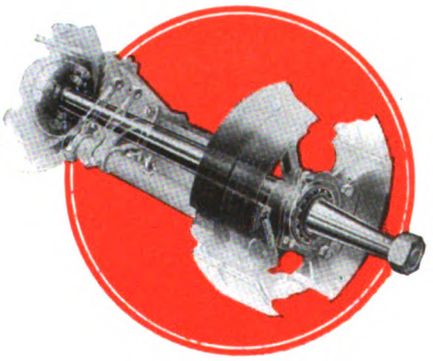


BALL BEARINGS offer less friction and have greater load capacity than any other type of anti-friction device invented. This is borne out by innumerable tests, conducted under every imaginable condition. This is particularly true under the wedging action of a thrust load of such proportions as is exerted on the worm. Furthermore, in the case of the worm, the use of the ball bearings is the only way whereby the elongation of the worm due to frictional heat can be perfectly compensated. This is accomplished by leaving the annular ball bearing placed at the front end of the worm, free to float.

Finally, and of great importance, ball bearings do not require the adjustment which other bearings, by their nature, must receive.

THE SHELDON WHEEL BEARINGS are enclosed in the main axle housing. They are thus protected against grit and other foreign matter when the wheel is demounted. At the same time the bearings are easily accessible, it being necessary only to remove the wheel and then the bearing retainer in order to get to them.

The shape of the hub itself gives greater strength where greater strength is needed, and furthermore allows the easy demounting of the wheels, thus making a change of tires quick, easy and economical.



NOT A SINGLE SHELDON DIFFERENTIAL, as far as we can learn has ever worn out. Notice how the gear teeth instead of being concave in design are broad and thick at their base, this providing ample protection against gear stripping and quick wear. Each bevel gear is supported *on both sides* by an intended hub inserted into a bearing ring in the spider. This insures absolute alignment and eradicates all possibility of faulty performance. Strength is further continued with efficiency in the hexagonal broaching of the differential gear to receive the axle shaft. A square insertion would permit quick wear, a splined insertion would weaken the metal. Sheldon design avoids both weaknesses.

THE BIG, HUSKY SHELDON DRIVE SHAFT is a forging 3½% nickel steel; accurately proportioned, expertly heat treated, and ground to size.

The distribution of strain along this length dictates a taper from the differential to the wheel bearings—thus a uniform strain is secured throughout and ample strength is provided where needed.

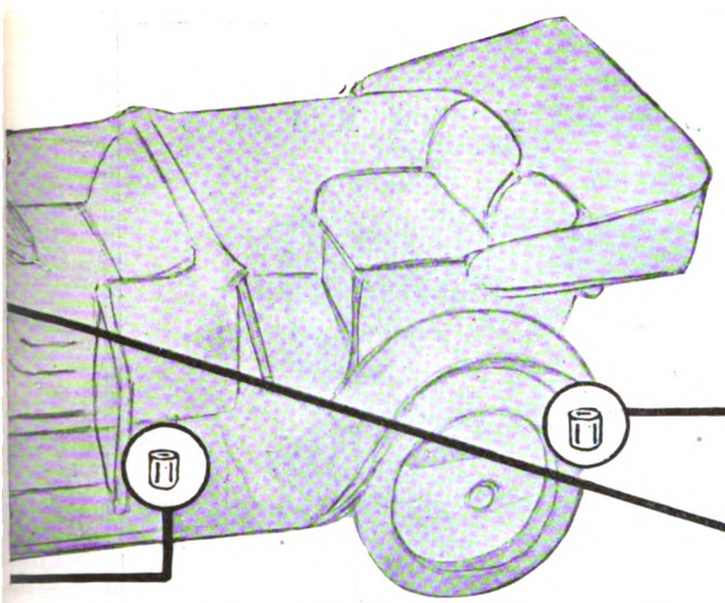
IT is important to remember that the service life of a car is determined by the life of its bushings.

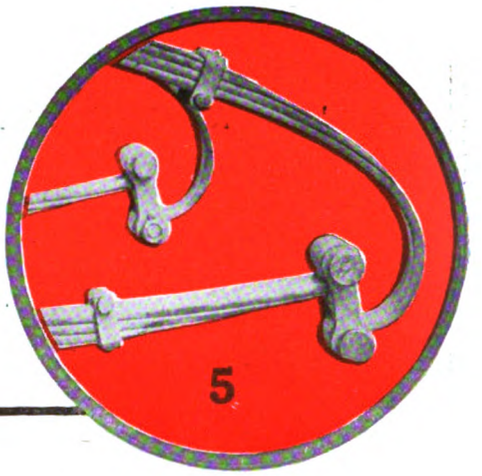
It is likewise important to remember that the service life of a bushing is determined by the amount of proper lubrication that it receives.

Ordinary bushings, when neglected, quickly wear out and cause early break-downs.

Therefore the leading manufacturers of trucks and passenger cars use genuine graphited oil-less bushings in those important bearing places that are liable to be neglected. In this way they safeguard and prolong the service life of their product.



Genuine graphited oil-less bushings are self-lubricating. They are "oiled for life" when made, and though oiling will not harm them, still they will run efficiently and smoothly without oiling or attention of any kind.



We also manufacture "Nigrum" (Impregnated Iron Wood) Oil-less Bushings.

4 reasons should sell

A Scientifically Perfected Ring

BURD Piston Rings represent the greatest advancement in piston ring manufacture of the past decade. They are the work of mechanical experts. The result of years of experimentation.

The BURD Guarded Opening seals the power in the cylinders. It turns waste power into extra power. No other piston rings have this feature. It is exclusively BURD. And so no other ring assures the perfect and constant piston ring fit that BURD offers.

A Nation-Wide Advertising Campaign

Full page advertisements in the Saturday Evening Post are appearing regularly. They are educating motor car owners to the vital importance of perfect piston rings in motor performance. They are proving to them that BURD Rings excel — and why.

And so just as motor car owners are demanding certain axles, bearing and lighting systems, they will now demand BURD Piston Rings.

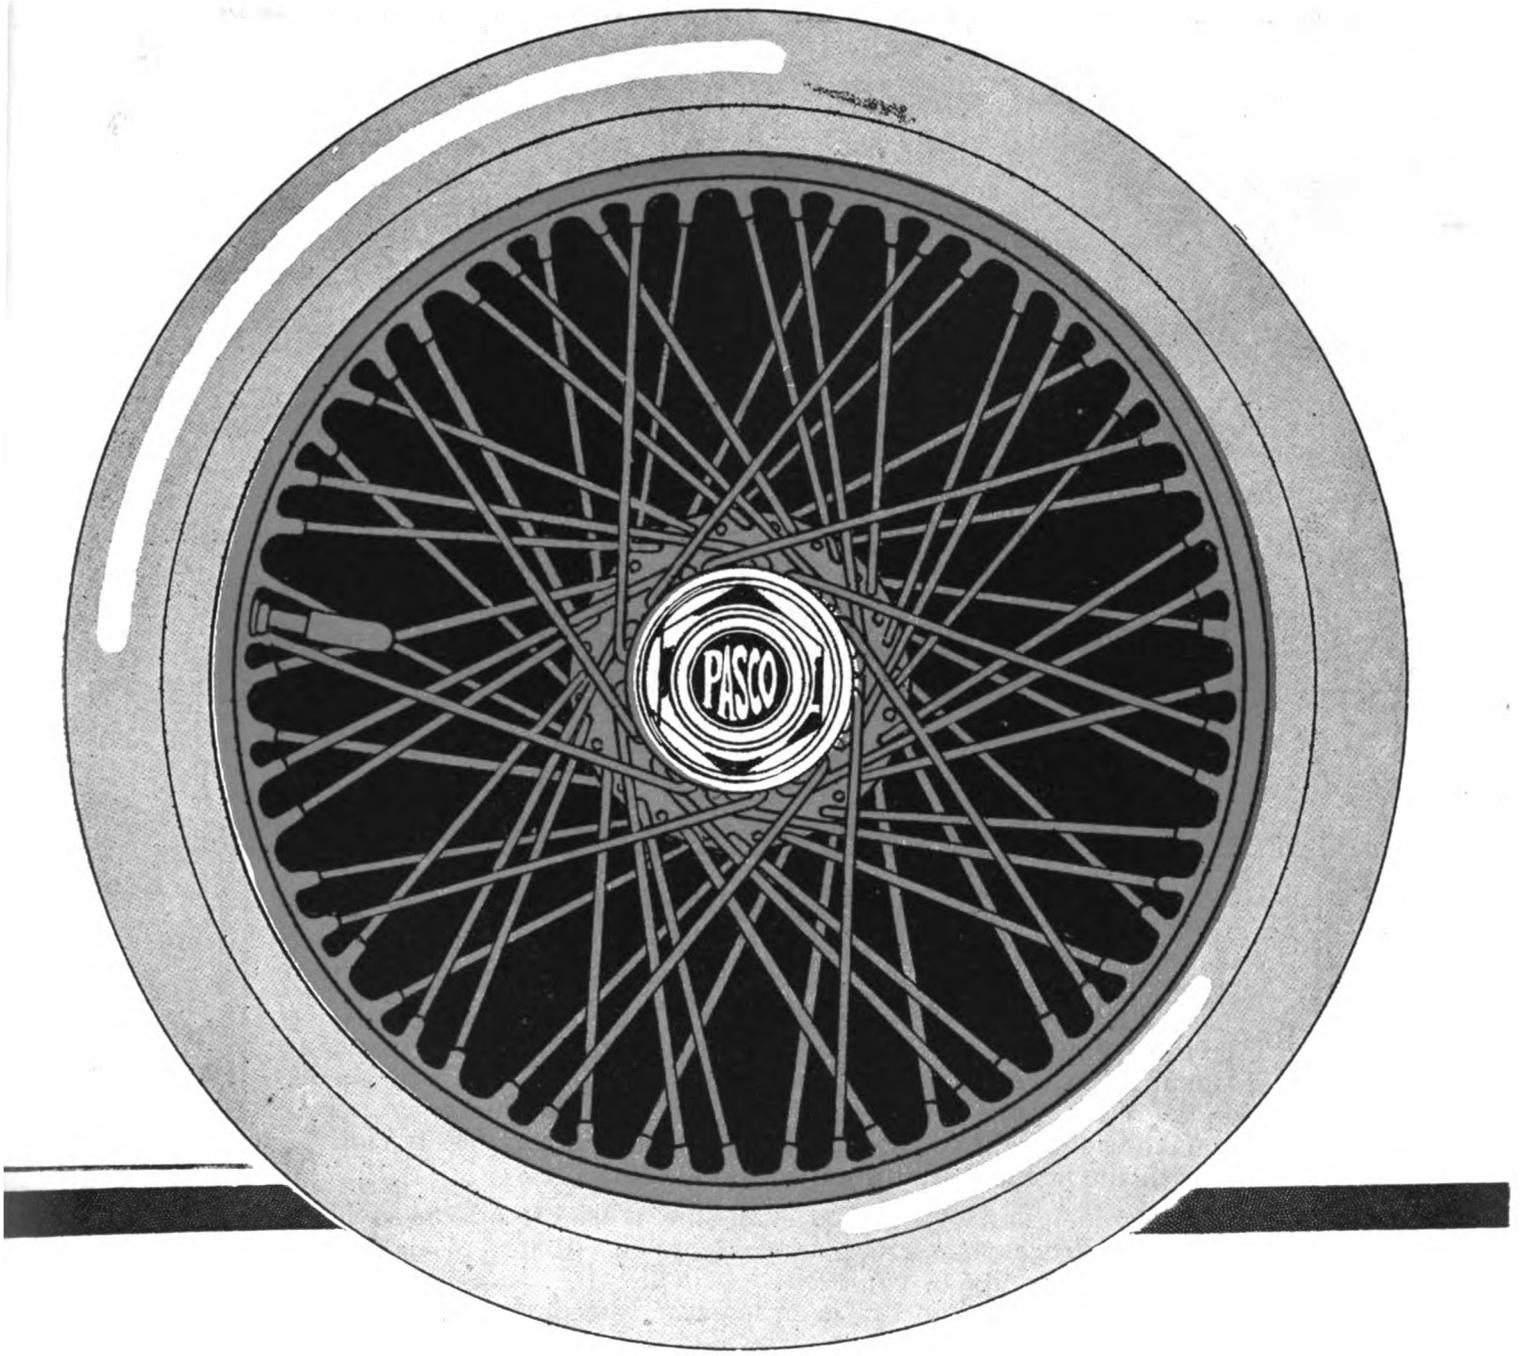
PASCO WIRE WHEELS have 3 Exclusive Patented Features in which lies the Secret of their Lightness, Dependability, Utility and Beauty

PASCO TRADE MARK

Note the Simplicity and Accessibility of Parts

The three exclusive Pasco features are of tremendous importance because they affect the entire wheel—make it stronger, more enduring, easier to change and more economical.



(1) **The Web**—All spokes in the Pasco Wire Wheel cross four other spokes—as against two or three crossed spokes in other makes. This forms a double web which is stronger than in any other wire wheel and 60% stronger than wooden wheels.

This distinct improvement is made possible by the patented four series Pasco method of Rim Punching and Spoke Lacing.

(2) **The Hub Cap** is made of a strong, indestructible metal that stands up perfectly in collisions, due to crowded traffic conditions, where aluminum, brass and other soft metal compositions will strain or break. It is sturdy, massive looking, yet attractive.

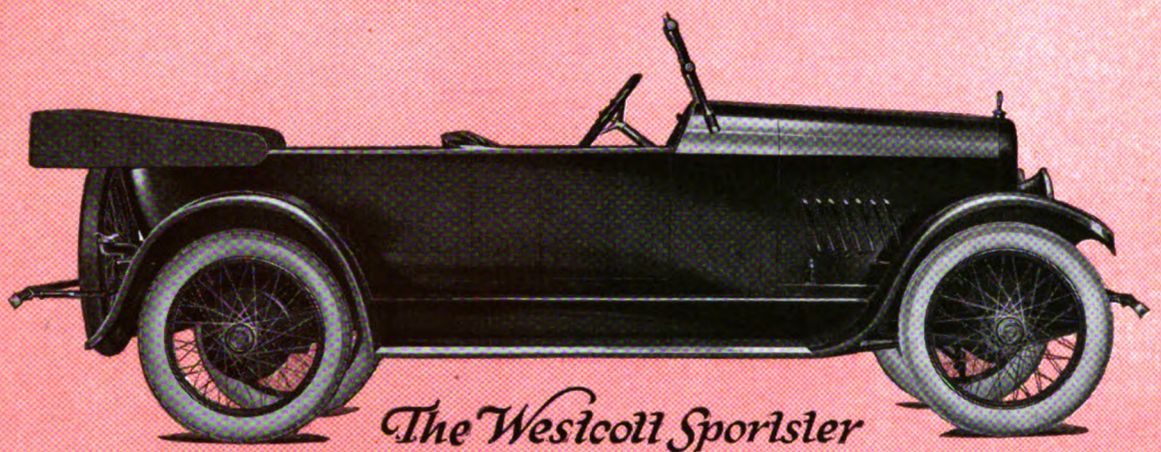
(3) **The Safety Locking device** absolutely prevents the wheel from working loose or coming off from a

Digitized by Google

moving car. This exclusive, patented feature is positive insurance against accidents from such a cause.

The hub cap and wheel are locked on to the threads of the inner fixed axle with a vise-like grip and can only be removed by using the Pasco wrench.

The tire saving qualities of Pasco Wire Wheels, their lightness, their shock absorbing construction, the speed and ease with which they can be replaced on the road—all these factors make for genuine economy in upkeep cost and a saving in time and trouble.



Pasco Wire Wheels give to a car an air of distinctiveness and beauty and an impression of speed and class which will appeal to all motorists.

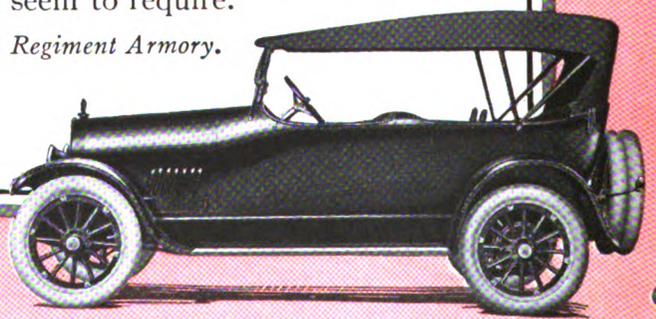
The Westcott Sportster

$2290 f. o. b. Springfield, Ohio
Wire Wheels $100 Extra. Price includes Cord Tires and Bumpers front and rear

THIS new pre-season Sportster is the latest evidence of the Westcott policy of keeping the Westcott Six well in advance not only in mechanical progress but in development of design and completeness of equipment.

To the engineering excellence and exclusive construction features that distinguish the Westcott from a practical standpoint, this new model adds the dashing lines, richness of finish, and wealth of accessories that will make it a delight to those who are satisfied in cars, as in clothes, only with the fashions that are a season ahead.



With the inclusion of the Sportster, the Westcott advanced ideas in motor car construction are available to distributor or individual buyer in just the type of car desired, whether the purchaser is concerned with winter comfort or is anticipating the preferences that will prevail in the months to come.

To see the Westcott line at the Show, to study the Westcott Specifications, and to examine the Westcott workmanship is to realize why the Westcott is bought by the man who wishes to represent or ride in a car that offers more in performance and appearance than present standards of motor car value would seem to require.

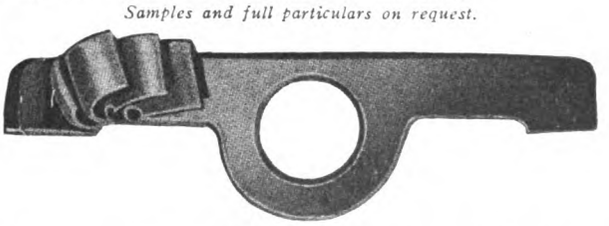
Tractor Service Is Hard On Bearings

LAMINUM

Makes Adjustments Easy



It has been said that the bearings were the weakest point of the present-day tractor. The work is so severe and the demands upon the bearings abnormal that excessive wear seems inevitable.

Loose bearings are an abomination, and anything that will enable wear to be taken up quickly and easily is a real boon to everyone connected with a tractor, from maker to user.

Laminum solves the problem. It makes reductions the work of a moment. A penknife strips off enough layers to make the shim the right thickness. The surface is as smooth and uniform as when first used. It makes a perfect adjustment possible by unskilled labor in very brief time. That's a mighty important consideration to tractor buyers. It's also a good reason why you should use shims made of Laminum.

Samples and full particulars on request.

Auto-Lite

Starting, Lighting & Ignition

Modernizes Motor Cars!

What one thing more than any other makes the modern automobile so convenient and safe?

Surely the perfection of the electric starting, lighting and ignition adds marvels to the ease, comfort and efficiency of any make of car.

You can hardly tolerate the thought of a car without it.

The world is largely indebted to Auto-Lite for the wonders achieved in this work.

Auto-Lite originated the six-volt principle, separate unit, now the standard of highest quality and efficiency.

This is why Auto-Lite is the world's largest company devoted exclusively to making starting and lighting systems for motor cars.

The intrinsic merit of its product has won supreme leadership for Auto-Lite and is your guide in the purchase of your next car.

What Keeps the Gears Silent?

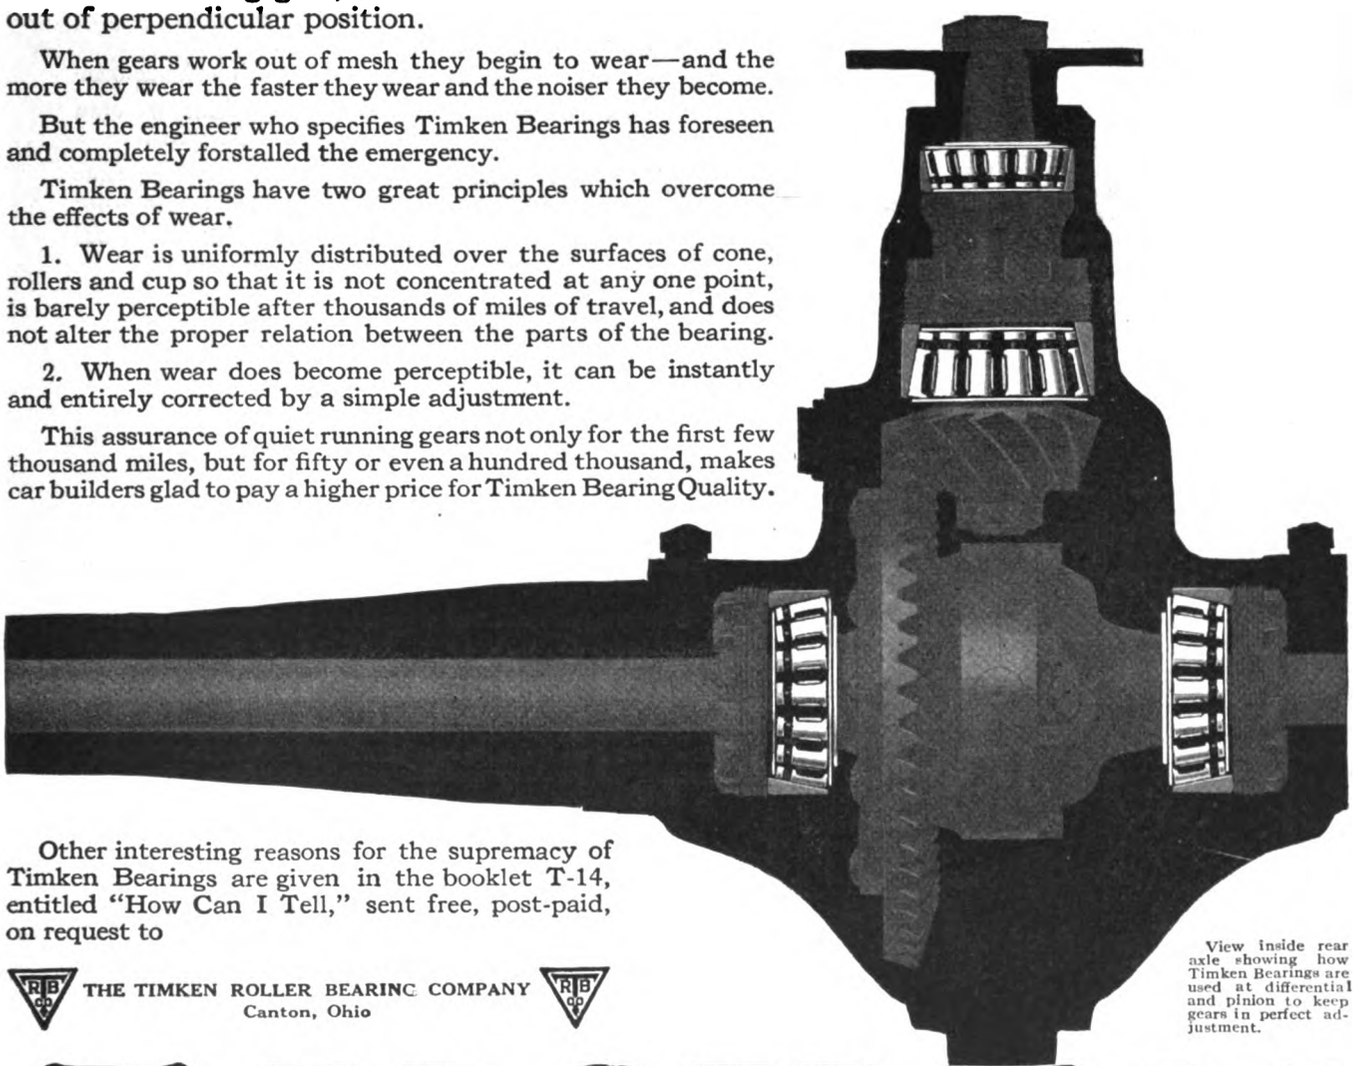
Smooth, silent operation of rear axle gears is one of the great objectives of the car builder's engineer.

He specifies gears mechanically and mathematically correct, but he must also provide one other essential—protection against *wear*.

The big ring gear has the whole dead weight of the car dragging it back. The little pinion gear at the end of the propeller shaft says it must go forward.

If the bearings supporting these gears wear loose, under pressure of conflicting forces, the pinion will climb on the ring gear, and the latter will be thrown out of perpendicular position.

When gears work out of mesh they begin to wear—and the more they wear the faster they wear and the noiser they become.



But the engineer who specifies Timken Bearings has foreseen and completely forstalled the emergency.

Timken Bearings have two great principles which overcome the effects of wear.

1. Wear is uniformly distributed over the surfaces of cone, rollers and cup so that it is not concentrated at any one point, is barely perceptible after thousands of miles of travel, and does not alter the proper relation between the parts of the bearing.

2. When wear does become perceptible, it can be instantly and entirely corrected by a simple adjustment.

This assurance of quiet running gears not only for the first few thousand miles, but for fifty or even a hundred thousand, makes car builders glad to pay a higher price for Timken Bearing Quality.

View inside rear axle showing how Timken Bearings are used at differential and pinion to keep gears in perfect adjustment.

Other interesting reasons for the supremacy of Timken Bearings are given in the booklet T-14, entitled "How Can I Tell," sent free, post-paid, on request to

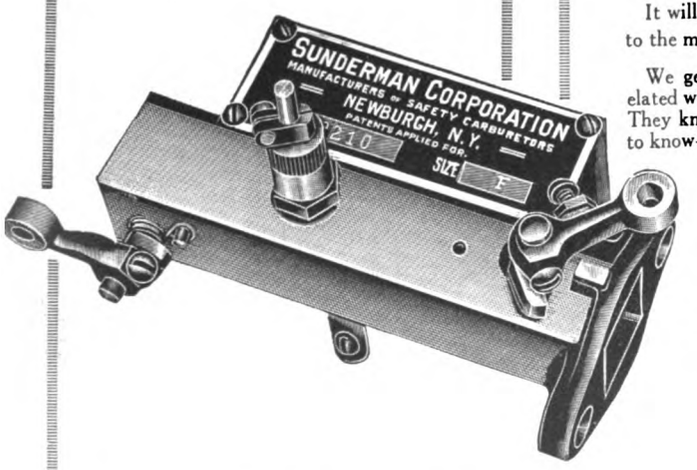
SUNDERMAN
Vacuum Carburetor



$6

F. O. B.
Newburgh

For FORD and METZ

For all other cars the prices are $8 and $10, depending on the fittings required. Its service is supreme on all makes and models of cars.

See us at the Chicago Show— Armory Balcony, Booth 5.

Your Carburetor Is Leaking

unless you've already equipped your car with a Sunderman.

You'd sew up a hole in your pocket, or else buy a new pair of trousers, wouldn't you?

Every time you turn your motor over, you're letting some good, hard-earned coin of the realm slip away from you without getting anything for it, unless you have a Sunderman Carburetor.

You Can Stop This Leak With a Postal Card

Just tell us to send you a carburetor (give the make and model of your car) and prove to yourself what the Sunderman will do.

It will positively save from 30 to 50% in your gasoline or other fuel consumption—that means it will give you from 43 to 100% mileage increase. We're proving it every day.

It will give your motor more power than it ever had—unless it is ready for the junk pile. Even then it will give it more pep, punch and pull than it has had in a long while.

It will give you better hill-climbing—the surest claim we make—an absolute, unfailing certainty. It will give your engine greater flexibility—a wider range of speeds, low, high and intermediate, taken without "bucking"; a smooth, swift acceleration or slowing down that has hitherto belonged only to the sixes, eights and twelves.

It will give your car a livelier getaway, a quick, sure pick-up, responding to the motor's demands like a great-hearted athlete who's bound to win.

We get in every day's mail testimonial letters from car owners who are elated with the Sunderman Carburetor's performance in power and economy. They know—and we know—what the Sunderman will do. We want you to know—you have ten days to prove it. Send us an order today.

Dealers: There is no better or more favorably known carburetor on the market today. We back it with consistent advertising. We make fine selling arrangements with the right people. See us at the Chicago Show, or write at once.

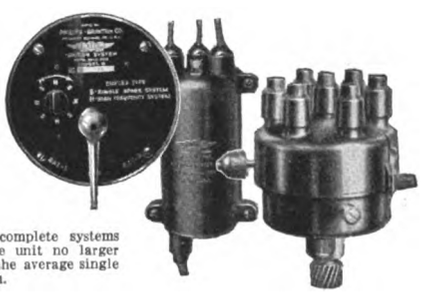
"coming home they sold her some poor gas, but with that switch on 'H' she never had to shift once."

FOR when she threw the switch to "H" the motor, which has been missing badly, immediately responded to the flood of sparks turned loose by the Philbrin High Frequency System.

That High Frequency System delivers a thousand sparks a second to each cylinder in its regular firing order. There's no mixture, even though poor, that won't give way before that stream of fire.

But the High Frequency is a secondary system to the Philbrin Single Spark System. Most of your running is done on the latter system with its hot, uniform spark, hottest at low speeds.

This system will fire a lean mixture perfectly and give your engine the power, speed and "pep" that every motorist considers his heritage.



The efficiency of Philbrin Single Spark Ignition is due in no small part to the Philbrin Contact Maker and Condenser, which provide for ample saturation of the coil and an instantaneous break, assuring a full-bodied, powerful spark with extreme y small current consumption.

Philbrin Duplex Ignition, by combining two distinct systems under one control, accomplishes results that could not be expected of any single system alone. And each system, separately, has been developed to the highest point of dependability and efficiency.

Made in sizes for all cars, with special mountings for magneto replacement when required. Our trade policy assures Jobber and Dealer an attractive margin of profit. Territories now being assigned. Write at once.

See Our Exhibit at the Chicago Automobile Show, Booth 87.

Why the Maxim Silencer Reduces Back Pressure And Silences BOTH Exhaust Noises

As to Back Pressure

The Maxim Silencer whirls the exhaust gases. It does not stop them suddenly or bandy them to and fro among baffle plates, or squeeze them through tiny holes and tortuous channels.

Have you ever seen waves breaking against a wall, or water suddenly deflected from its course and made to run at a right angle to that course? If so, you remember the inevitable reverse wave that goes rippling back along the current.

Now, suppose this water, instead of hitting a sudden obstruction and being sharply deflected, merely runs into a whirlpool. There is then no reverse wave—no back pressure. And if the outlet to this whirlpool be in the reverse direction to the whirl of the pool it is easy to understand that the water leaving will be the water that has slowed down and drifted out.

The Maxim Silencer acts in just that fashion. It starts the gases whirling and uses up their velocity in this whirling motion. They leave the first chamber to enter the second through an opening in the reverse direction, so that only that portion of the exhaust that has slowed down passes through.

The exhaust is thus slowed down and cooled off (by contact with the walls of the second or outside chamber) without being stopped or sharply deflected. Therefore, practically no back pressure is developed. It is the simplest—and most efficient—method.

As to the TWO Noises

Mr. Maxim's study of gun report noises disclosed the fact that there are two separate and distinct noises produced by the discharge of a fire-arm. One is caused by the sudden liberation of high pressure gases; the other by the bullet in its flight through the air. The latter is not a "whistle" or "shriek," but a sharp "crack," exactly like the crack of a whiplash.

Two noises of similar character are made by an automobile exhaust. One is caused by the sudden expansion of gases abruptly liberated into the atmosphere; the other by the high velocity with which these gases rush through the outer air.

The Maxim Silencer is designed to quiet both these noises; the first by a whirling motion of the gases, causing centrifugal pressure against the outer walls of the Silencer chamber. This pressure slows up the gases and sends them into the atmosphere in a thin, creeping stream, instead of a solid, rapidly moving mass.

It also cools them against the walls of the chamber, so that they are more nearly the temperature of the outside air.

The second or "cracking" noise, caused by the speed with which the exhaust rushes into the atmosphere, originates under the exhaust valve, and when it reaches the Silencer it is already a noise or sound wave. Being such it has no inertia and will turn a corner as readily as advance forward. When it issues from the first to the second tubes therefore it starts around in both directions. Every time it passes the outlet of the second tube some of the wave escapes, while the rest continues on around the endless chamber.

This sound wave, or noise, is thus split into a great many smaller waves, and its strength and sharpness materially lessened.

The MAXIM-SILENCER

Next year the "Maxim-Equipped" cars will have the call. Motorists will learn a great deal about mufflers this winter, and they are going to ask for a "Maxim-Equipped" Car. It means more power, less fuel, no blowouts, a muffler that cannot rattle or come loose and that will outlast the car itself.

Write at once for full particulars and very generous terms.

"Have used
set of Cork Insert Transmission Linings on my Ford for
10,000 miles
and they are
good as new"

—so writes Edward P. Schafer of Millvale, Pa., and his is a typical Ford owner experience with Cork Insert Transmission Linings. Outwearing two to three sets of ordinary linings, they end the nuisance and expense of frequent replacements. Throughout their long wear they give wonderfully efficient service. They stop the grab, slip and chatter — replace it with velvety smooth transmission action. They eliminate the heavy vibration and strain on mechanism and the Ford rear end. They make the Ford brake *brake*. They require less pressure on the pedal. They permit the hauling of a heavier load. Service considered, Cork Inserts are by far the most economical linings you can buy. Your dealer has them or can easily get them for you.

Dealers: Cork Insert Transmission Linings and Fan Belts give you a line of *good profits* in place of a small margin staple. Sales have jumped ahead every month the past year. Order Cork Inserts from your jobber and cash in on this winner.

THE HOOSIER CLUTCH

The HOOSIER is a simple, self-contained, absolutely effective clutch, guaranteed to give satisfaction to the most discriminating engineers and users.

Any one can adjust the HOOSIER Clutch for wear, as there are no bolts to loosen, no levers to adjust, and no pressure is brought to bear on the clutch pedal, as the clutch is adjusted while engaged.

To adjust, simply loosen the screw which holds the adjusting bushing lock and turn the adjusting bushing to the right the required distance, then lock again.

This feature makes it possible to adjust the spring pressure to the desired tension for any driver—a good selling point.

With the exception of the plates and friction discs the HOOSIER Clutch is entirely self-contained, which makes its assembly in the chassis a very simple operation.

Extra wide friction discs are used, which gives larger gripping surfaces, and insures longer life and fewer adjustments for wear.

The HOOSIER Clutch is made in the standard sizes, both Unit Power and Amidship types, and interchanges with other makes of clutches of similar design.

We guarantee first class material and workmanship, and can easily take care of your delivery requirements.

The Brains Behind the Battery

Even as every great human achievement is the dream of some one master mind forged into actuality—so the Permalife Battery is primarily the product of the brains of one man.

Frederick Wright, electrical genius, whose name is writ high on the honor roll of inventors, is the master mind back of Permalife.

This man possessed the will and the grit and the faith that led him struggling through years of bitter disappointments and failures, to at last bring forth to the world the one truly great storage battery.

In Permalife Wright built—

A battery which delivers a higher discharge for a greater length of time than any other ever produced.

A battery which is absolutely free from harmful sulphation.

A battery whose plates are so designed as to be positively protected against buckling, and which are interspaced with electrically treated separators to prevent short circuiting.

A battery whose plates are *packed* (not pasted) with an active material so permanent as to give them supreme durability and yet so porous as to facilitate the quick chemical action of the electrolyte.

In short—a battery which is so perfect in design and construction as to stand alone in its capacity for service and long life.

Nothing succeeds like success. Frederick Wright was sought by great interests and told to name his own terms, but he preferred his independence. The end justifies his judgment.

Today, in the model Permalife factory at Poughkeepsie, Wright's dream has reached fruition. Here under ideal conditions with a corps of trained assistants and expert workmen operating under his personal supervision, Permalife Batteries are being produced to satisfy his most exacting specifications, and in ever-increasing quantities to meet a tremendous, healthy demand.

The merchandising plan of the Permalife Co. is unique. It places before the dealer a plan by which the bulk of the local battery business can be gained and held and made to yield rich returns.

Write for this co-operative proposition today.

Don't Buy Glass—Buy Performance

YOU can't buy a good lens on appearance or on claims alone. PERFORMANCE forms the only sound basis for your selection.

The Dillon Multi-Vision Lens **does** what other lenses **claim to do.**

The average lenses prevent glare, but in so doing **restrict** the light.

The Dillon Multi-Vision Lens, on the other hand, gives you TWICE the lighted area instead of decreased vision. It gives you a SQUARE path of light instead of a narrow, fan-shaped shaft. It gives you long-range light for over 500 feet ahead and for over 25 feet on either side.

So brilliant, yet so glareless, is Dillon illumination that you can ride as safely at night as by day.

In addition, the Dillon Multi-Vision lens possesses distinction; it is so made that it cannot work loose in the rim and it cannot break from contraction or expansion.

You must SEE a Dillon Lens to appreciate its worth. You must buy the Dillon if you want dependable performance. See your dealer today.

Why the Dillon is More Efficient

THERE are three vital features of Dillon design, each of which contributes to the **ultimate** in light distribution. The mottled glass diffuses the light, while the clearer portion below illuminates the road at the side and front—hence a square path of light and, therefore, twice the lighted area. The bull's-eye in the center, **a distinguishing feature of the Dillon Multi-Vision Lens, concentrates and magnifies the central beam of light below eye-level. These otherwise dazzling rays are scientifically neutralized, diffused and deflected from the clear glass immediately above the bull's-eye.**

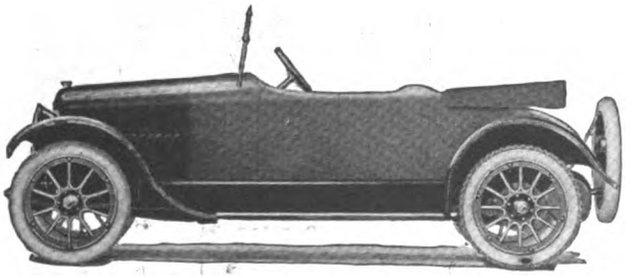
By World's Champion Light Six

6,202 Miles With SEALED Hood, Clutch and Transmission

CHICAGO to the Pacific Coast and back—no CHANCE to touch the engine --no chance to even LOOK at clutch or transmission—that is the latest wonderful record of the ELGIN SIX.

The Valve-in-head Motor never faltering on the steepest inclines, in the deepest mud nor the heaviest sands—



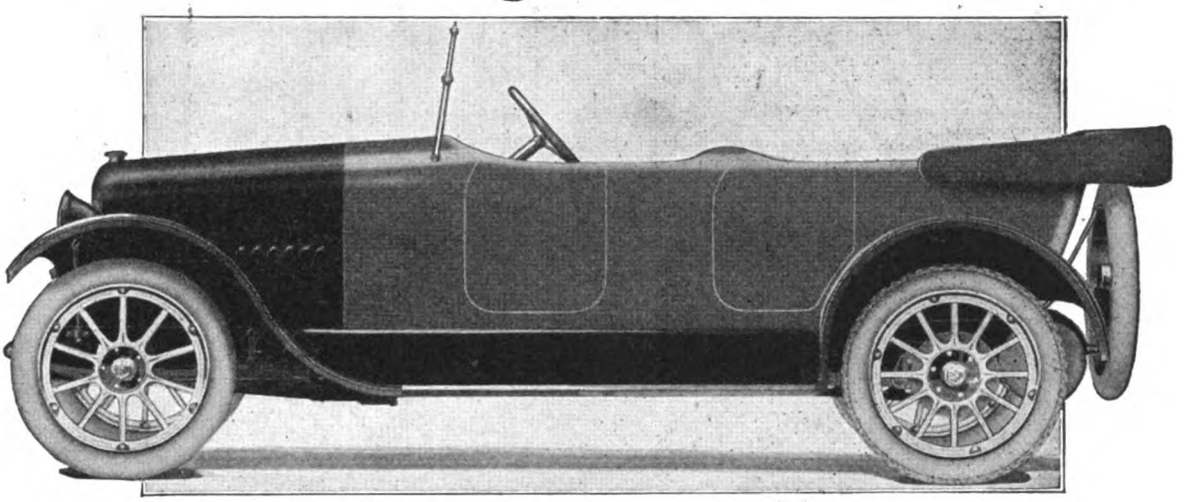
The CLUTCH holding on mile after mile of steepest mountain climbs—

The BRAKES holding fast on mile after mile of downward plunges—where slipping meant death—

What eloquent proof of the 100% *stamina* and *dependability* of this strictly stock ELGIN SIX.

And Economy—19.4 miles to the gallon of gasoline.

Elgin Six



Elgin Six 4-Passenger Roadster, $1095
F. O. B. Chicago

A car for business and professional use, as well as for all-'round driving. Roomy enough for four people, yet not too large for one or two. Front seats divided. Beautiful yacht-line design. A popular, practical model. Same chassis as touring car, with 117-in. wheelbase, valve-in-head motor, etc.

A full Page Ad. on this Story appeared in the Saturday Evening Post, January 12, 1918

Digitized by Google

Victory Scored

Elgin Six 5-Passenger Touring Car, $1095 F. O. B. Chicago

A roomy, impressive car. 117-inch wheelbase. Valve-in-head motor. Quality upholstery and finish throughout. Flexible, powerful, smooth running and easy riding. The most economical car of its size. Beautiful, durable. A family car which old and young alike enjoy.

ENGINE, clutch and transmission performed *without adjustment—without repair*—for two solid months of continuous travel under the roughest usage.

The Elgin climbed and descended the precipitous slopes of the Rocky Mountains; threading its way along tortuous, rock-strewn mountain trails; plunging through unbridged streams.

Without a break the car ran perfectly in the freezing, rarefied atmosphere above the clouds; and cooled perfectly in 132 degrees of desert heat, where heavy pulling increased the difficulty of *keeping* a motor cool.

A broken fan-belt—compelling the car to travel a thousand miles homeward *with a still fan*—a performance almost unbelievable—added a crucial test.

The record-breaking run from Chicago to Miami, Fla., the Minneapolis-Fargo dash, and many other famous ELGIN winnings had fairly earned for the ELGIN the title of "World's Champion Light Six."

Hence, when the officials of the Chicago Motor Club determined to secure authentic data on the condition of the two great national highways—The Lincoln Highway and The National Old Trails Highway—they selected the ELGIN SIX because of its previous wonderful records. It was made the "Official Scout Car," traveling under the auspices of the Chicago Motor Club, the American Automobile Association, the Detroit Automobile Club, and many other Associations affiliated in the Good Roads Movement of America.

In the Service of the U. S. War Department

But the greatest honor was conferred upon the ELGIN SIX when Secretary of War Newton D. Baker, in a personal letter, appointed it Official Scout Car to report transcontinental road conditions to the War Department—to gather information that may prove most valuable to the War Department in emergency movements of troops and supplies.

It was a commission of honor for the ELGIN. No car had ever been sent on an errand so important to this Government. No car had ever been charged with a service so distinguished.

Successful dealers are fast coming to the Elgin Six.
A highly profitable connection may be awaiting YOU.
Wire for territory and full details.

Master of the Load on any Road

Prompt Deliveries

Don't be held up now on delayed deliveries. Don't lose both sales and reputation in these difficult times by pushing any truck on which you cannot depend. Sell the Master—deal with a concern making trucks alone, equipped to fill your orders *on time.*

Today, as never before, there are opportunities for dealers to make enormous profits in the truck business. The press of government orders makes truck deliveries surer than railway deliveries, and the demand for real, service-giving trucks must soon exceed the supply. Sell the reliable MASTER—your orders and re-orders are delivered *on time.*

When Mr. Edison Speaks—

When he discusses electrical innovations, we listen to him with respect.

When Signor Marconi speaks of wireless, every word has weight.

When Mr. Schwab discusses the steel situation, he is sure of an interested audience.

Whenever recognized authority expresses itself, we can rely upon its opinions and judgment.

So, when the motor manufacturers who are known to maintain the highest structural standards adopt Eisemann Magnetos as standard equipment, isn't it conclusive evidence of superiority?

In the truck field, where the hardest tests come, 81 manufacturers have done so. Most of the recognized leaders are included in that number.

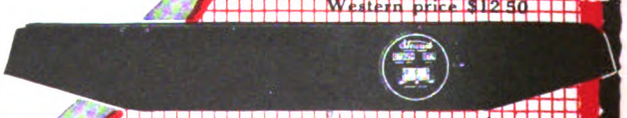
Progressive Dealers Know It Pays to Sell Leaders Only

LIVE dealers everywhere—men who do a big business and are making big money—know by experience that it pays to sell *Leaders Only*. They stock, sell and feature Stewart Products. The wide demand for Stewart Products is extremely significant to the wise dealer. It points out to him the unmistakable trend of public opinion—the tremendous demand for the best known and most widely advertised automobile accessories on the market.



The dealer who has achieved really big success does not waste his time, energy and money in trying to "put across" unknown accessories. He banks on a steady, consistent "turnover." He handles the one established line—the one that is universally accepted as a standard. He carries a complete stock of Stewart Products.

Determine right now to sell nothing but Leaders for 1918. Concentrate on, "boost", feature and sell Stewart Products—the fastest-selling and easiest-to-sell of all automobile accessories.

What the Laboratory Decrees the Foundry Must Execute

Determining the right formula in making alloys for bushings and bearings is a task worthy of man's best skill and talent, yet the work the laboratory does is simply a beginning.

So, in *Lynux* plants, when the metallurgist has finished his task, when he has decided what physical properties the bearing should have and has prepared the "mix," it is up to the foundry to follow his instructions to the letter.

How Certainty is Assured

In this, as little as possible is left to chance — so little, in fact, that when the laboratory decrees, the foundry must execute.

The laboratory's instructions go to the foundry in chart form. By this chart, the metal room is guided in weighing up the charge. And right here an important factor — bonus — steps in.

Those who weigh the metal — those who melt it — those who pour it into the molds — all are "on bonus," earning extra rewards for work well done and paying the penalties for their failures.

Every Worker an Inspector

Therefore, the natural desire of every good workman to do his work well is sharpened by the desire for the bigger pay that goes with good work, and he watches sharply to protect himself against possible mistakes by others.

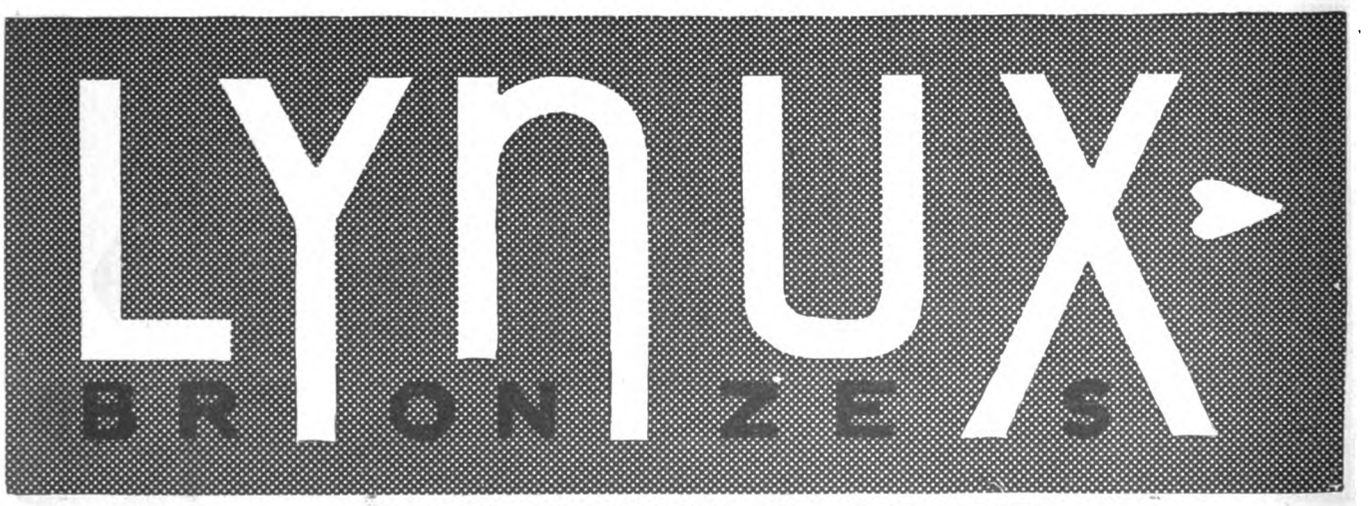
The man at the melting pots keeps his eyes open lest an error in mixing the charge make trouble for him. The man at the mold is quickly heard from, if by any chance the melting room burns the metal and he gets a "scrap" casting as a result.

To individual bonuses are added bonuses for departmental efficiency, and the correctness of every foundry operation is further insured by frequent and thorough inspections.

It is this kind of practice that distinguishes *Lynux* foundries from ordinary foundries, that makes *Lynux* alloys differ from ordinary alloys.

Lynux for Every Purpose

There are more than a hundred *Lynux* Alloys. We will help you pick the right one for the particular bushing or bearing job in question and supply the bearings rough or machined. Also, we can follow your own specifications as to alloy, if you desire.



Let us send you our monthly mailings on bearings. Address Dept. 45, Cleveland, Ohio.

Are you using LYNITE? If not, let us tell you about this group of aluminum alloys, which have proved so effective where light weight without sacrifice of strength is desired.

25th Successful Year

The New Haynes Open Car for Seven

LONG, low-swung and straight-lined, with high-arched, broad-chested hood, rakishly tilted weather-tight windshield, double cowl and wheel-form fenders, this new Haynes offering in a seven-passenger open car is proving a strong contender for the title of the season's favorite.

Front springs measure 39x2¼ inches. Rear springs are 58x2¼ inches. Their generous size and resiliency afford the extreme in riding comfort.

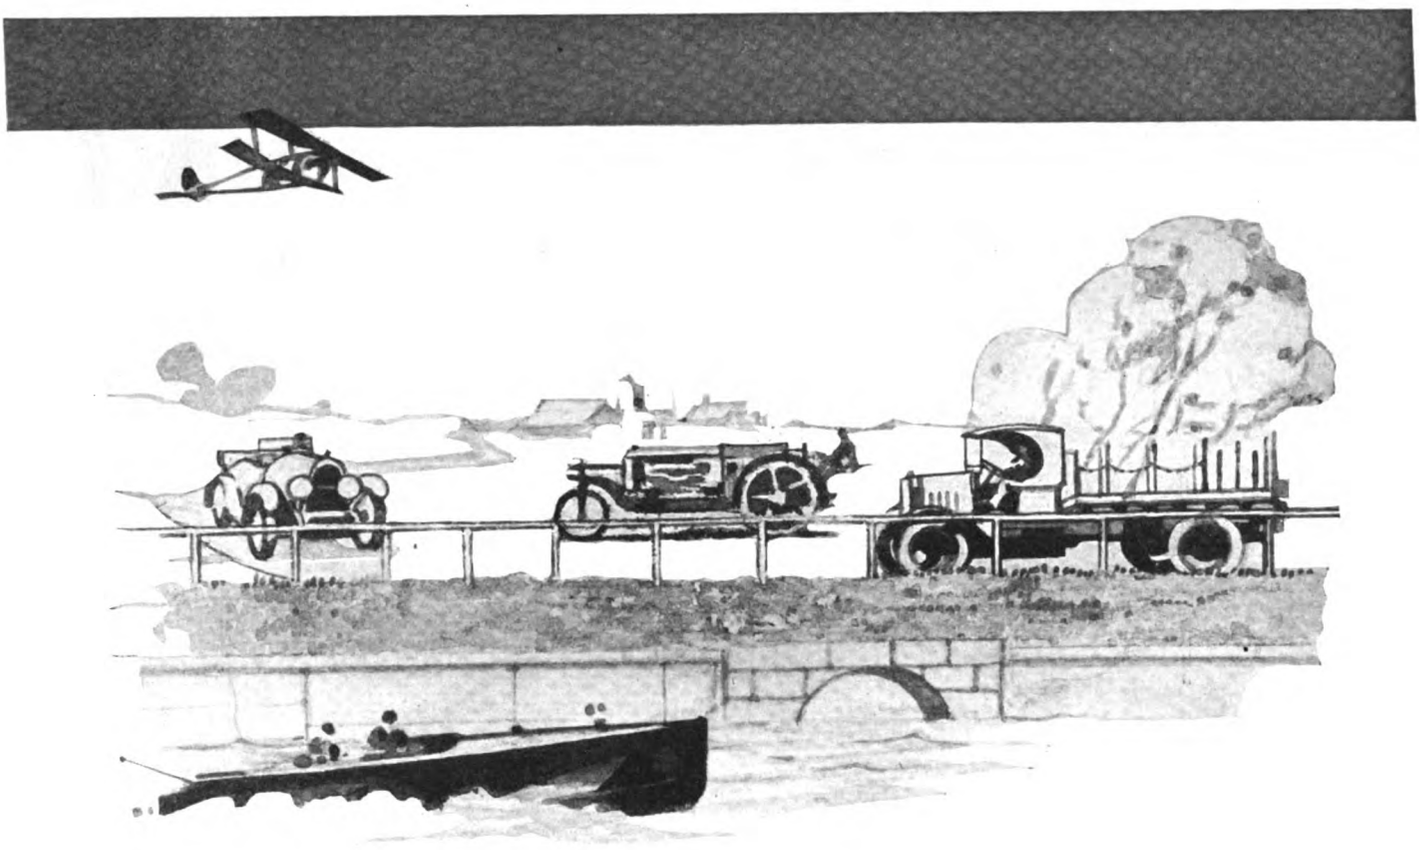
Six-inch frame side members preserve rigidity on uneven roads, avoiding squeaks, rattles, binding doors and sagging.

The finishes are beige brown, deep carmine and royal green. The upholstery is modishly fashioned in French pleats.

The center cowl panel is beautifully grained American walnut. Large auxiliary seats disappear within it. A parcel compartment and cowl light with switch are centered therein.

The motive power is the famous Haynes Light Six engine—that *mature* engine which has required no vital changes in three and a half years.

—The complete Haynes line includes eleven new settings for the Haynes "Light Six" and "Light Twelve" engines. National advertising is being extensively used. Live dealers have a live proposition awaiting their wires or letters. Address



THE HAYNES AUTOMOBILE COMPANY, 3 S. Main St., Kokomo, Ind., U. S. A.

Special Service To Manufacturers

The best equipment may be rendered ineffective by poor finishes. Many manufacturers lose time and money on this account.

To correct such conditions we established our "Better-the-Finish" Laboratory for the solution of individual finishing problems.

We will study your special necessities, make actual tests under conditions approximating those in your own work shops, and tell you just what finish will best fill your requirements.

We have been doing this very thing to the great satisfaction of many manufacturers for a number of years.

Why not see if we cannot better your finish? It will cost you nothing and may help you greatly.

Manufacturers handling government work should bear in mind that our experience in co-operating with firms handling similar work is at their disposal.

Museum of Finished Products illustrating the diversity of problems solved by "HILO" Laboratory.

The Whole Automotive Industry

—comes to us with its finishing problems.

Motor Car — Truck — Tractor — Trailer — Airplane and Motor Boat—are all exposed to the Common Enemies, Rust and Rot.

The Motor Car, Truck and Tractor are bumped and scratched, streaked with mud and oil, twisted and strained—they need a tough coating.

HILO

Enamels—Japans—Varnishes

The Airplane meets quick changes of temperature, leaves the ground in summer heat and in a few minutes is breasting a wintry storm—that requires extremely elastic finishes.

The Motor Boat is in constant contact with water—often entirely covered with spray and always subject to extreme moisture—a moisture-proof varnish is needed here.

It pays the manufacturer to protect his product with properly prepared varnishes, enamels, or japans. "HILO" finishes are made to fit each individual case. "HILO" Special Service tells the manufacturer how to correctly apply his finishes. It saves him those expensive experiments.

Write for our Bulletin No. 1. It contains information you can use—whether you buy from us or not.

DETROIT TRANSMISSIONS

DETROIT GEAR & MACHINE CO.

MODEL H TRANSMISSION

Amidship Type Truck Transmission for 1½, 2 and 2½-Ton Trucks
4 Speeds

A new design transmission of the amidship type which carries 4 speeds forward and one reverse. It makes possible a more even distribution of the weight of the truck and eliminates the whipping of a long drive shaft. Mounting is on cross members, permitting easy inspection and removal.

The logical transmission for 1½, 2 and 2½-ton trucks of the better class that are designed for strength. The transmission is in production and ready for immediate delivery.

Gears are 6-8 pitch, 1" width face, made from drop forged, heat treated high carbon 3½% nickel steel. Shafts are heat treated and carbonized alloy steel, mounted on ball bearings. Gear ratios are as follows:

High—Direct	Second—3.08 to 1
Third—1.76 to 1	Low—4.4 to 1

Weight, as shown, 145 lbs.

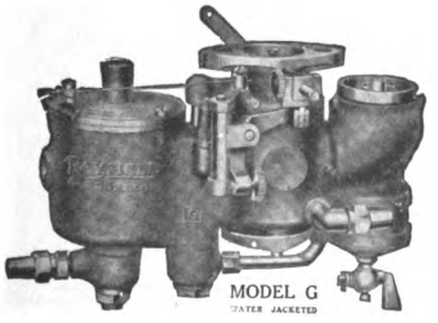
RAYFIELD CARBURETOR

The High Cost of Some Savings

PRUNING the pay-roll is often expensive. A cheap clerk makes costly mistakes. The extra expense of supervising him makes him a further liability.



Same with an inefficient carburetor: it wastes gasoline. And it needs endless supervision—*adjusting.*

If you're worrying along with a gasoline spendthrift—a carburetor not up to its job—you'll be interested in the Rayfield.

The Rayfield Carburetor is an expert in its line—guaranteed to give you from 20 to 50% more miles per gallon; and better all-'round performance.

Test one on your car; winter is a good time to do it. The Rayfield costs a bit more; but it's worth it. If you don't think so your money will be refunded; cheerfully.

★Hartford

THROUGHOUT motordom, here's a name to conjure COMFORT by —and SAFETY, CONVENIENCE, ECONOMY too, for that matter.

"Accessories" fails to adequately describe Hartford Automobile Equipment; "Essentials" is the more fitting term.

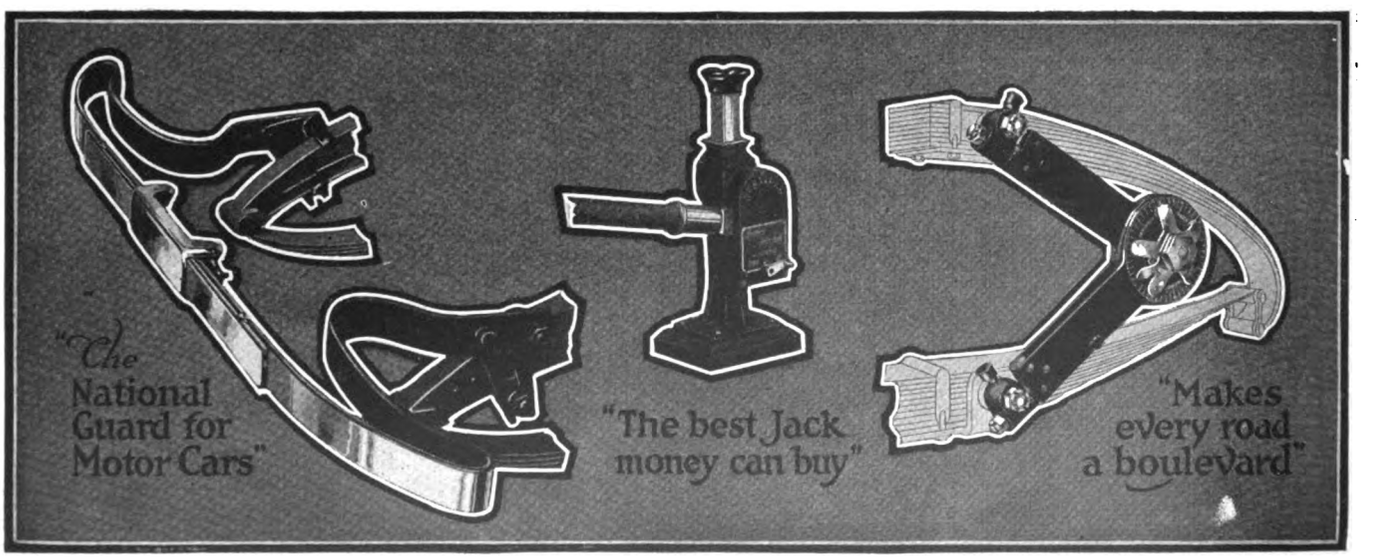
★Hartford SWIVEL TYPE SHOCK ABSORBER

A necessity for all who wish to render the range of motoring unlimited. It kills off road shocks, jolts and jars. It makes country byways as accessible and comfortably negotiable as city boulevards. In a word, it causes an automobile's springs to behave and that's the real secret of smoothly riding automobile.

★Hartford BUMP ABSORBER —more than a Bumper

It defines its function by its name, for it **absorbs the bump** of collision, effectively parrying the blow accompanying it. Thus, it protects not fittings alone but all the car from strain and damage and, its passengers, from jars. A formidable, flexible car guard that is just as necessary as collisions are inevitable.

★Hartford AUTO JACK



So conveniently efficient that no motorist who has seen it work has failed to mark it for immediate preference. A jack de luxe. Its smooth-working mechanism is turned on precision machinery from solid steel; its casing is tough, wear-proof malleable iron; its handle is long; its stroke is short. And yet more—it's handsome, too.

Let your visit to the Chicago Show include an inspection of these motoring essentials. All will be practically demonstrated

Why have 150 Car Builders adopted the ECLIPSE-BENDIX DRIVE as Standard Equipment?

Because the starting efficiency is much greater than with any other system.

Because the meshing of the gears is absolutely automatic. At the time of starting, the Drive gear automatically screws along the Drive shaft and meshes with the flywheel gear, and then cranks.

Because the demeshing after starting is absolutely automatic. After the engine is started the flywheel gear turns faster than the Drive gear and screws the latter back on the Drive shaft until it is out of mesh.

Because cast iron teeth without any chamfer not only make a great saving in cost, but are actually superior, being the simplest, most efficient and durable construction possible. The teeth are cut in the flywheel which is a natural gear blank. Stripping of these teeth by accidental starting when the engine is running is impossible, because of the automatic demeshing action.

Because back-fires are automatically protected by the shock-absorbing spring Drive.

Because there is no over-running clutch to stick or slip.

Because there is no resistance or two-point switch to burn out.

Because there are no shifting levers and pedals, with their complications.

Because it is simpler and has fewer parts than any other starting system.

Because it eliminates chains, which stretch, break and get noisy.

Because it minimizes gear noise in cranking by driving through a spring.

Because it is absolutely silent when the engine is running, being absolutely disconnected.

Because it permits of using a simple, small generator for constant running.

Because it permits of cranking the engine with the most efficient of all starters—a separate electric starting motor—and also more evenly.

Because it makes the two-unit type of starting and lighting system superior to any other and the most popular of all.

Because it requires the minimum of care and attention during the life of car.

Because it is regularly supplied and used as standard equipment with the following starting and lighting systems, on over 150 different makes of motor cars; and also on a large number of marine and aeroplane motors.

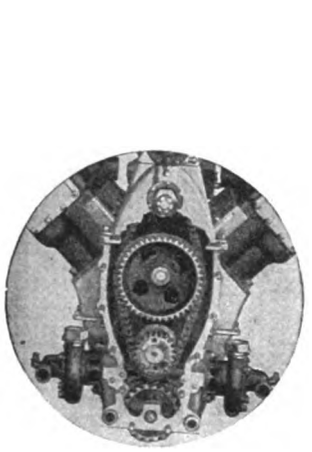
For MOTOR TRUCKS and TRACTORS



Our years of experience in chain making combined with the care taken in the various processes of manufacture and our rigid system of inspection make "Whitney" Chains accurate, strong and reliable.

"Whitney" Chains are "doing their bit" on the battle fronts of Europe, where dependability is the all-important factor and where failure may spell disaster.

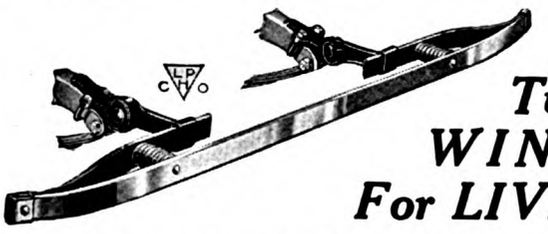
ENCLOSED CAR BODY MODE

More beautiful and luxurious than ever before, have been pronounced the H & K body designs, in hardwood-framed steel, under active production at the works in Philadelphia.

Illustration shows the latest H & K Steel Body for the Paige Sedan. The daring yet graceful lines, luxuriously upholstered interiors, the smartness and individuality displayed in this work, equals that of the most expensive custom-made, and appeals to all lovers of the beautiful in automobiling.

Our great works at Philadelphia are engaged on the finest enclosed body work for several of the foremost cars of the country—reflecting the buyer's keen appreciation of a really valuable and enduring product, made entirely complete, ready for application to the chassis, and now being shipped in large quantities daily.



Suggestion is made for your engaging space here for producing your requirements in the most successful steel enclosed bodies; steel stampings of all kinds; complete cushion and back springwork, etc. Inquiries and drawings to the nearest office.

GALVANIZE RIMS AUTOMATICALLY IN MEAKER UNITS

Deposit a heavy, bright, uniform coating of pure zinc on all rims for your cars—the galvanized finish that looks good and is good.

Well galvanized rims are bright when they come from our machines and just as bright after they have made many thousand miles on your machines.

Superior Meaker Galvanizing will not cost you as much to produce as out-of-date, inferior, dark-colored, thin zinc coatings that do not even protect rims from rusting while they lie in storage.

Forward us a set of rims and felloe bands and we will give you some interesting figures.

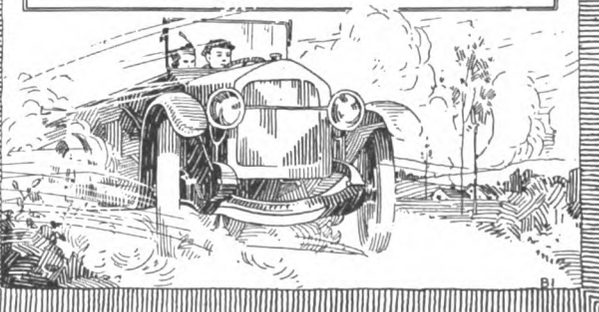
MEAKER GALVANIZING COMPANY
1249 Fulton Street Chicago, Illinois

Save Extra Auto Tax

Every ounce of energy wasted by leaky cylinders is an *extra* tax on your auto or truck. And that tax grows with advancing gasoline prices.

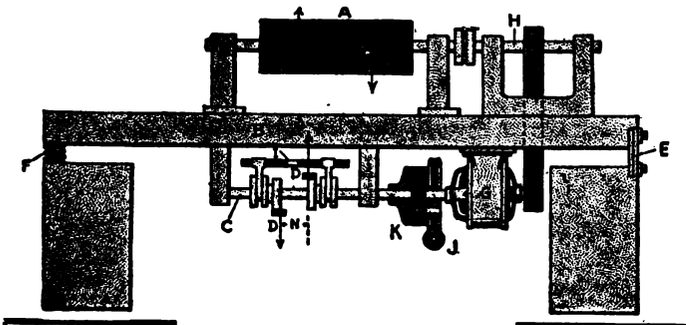
Stop this costly leakage with Ever-Tight Piston Rings.

Accurately machined from fine-grained, springy grey iron, they hug the cylinder wall closely without binding. Conform exactly to out-of-round cylinders, saving reboring. Gas can't leak through or by them.



Ever-Tight Piston Rings are safeguards against imperfect combustion with resultant carbon deposits; against smoky exhaust resulting from oil leaks. They increase engine efficiency from 15% to 25%, thus reducing running expense.

Demand Ever-Tight Piston Rings of your dealer or repair man.



EVER-TIGHT PISTON RING CO.
1428 Chestnut Street :: :: Saint Louis

This perfect three-piece construction justifies the name—EVER-TIGHT. These close fitting right angles are absolutely gas tight.

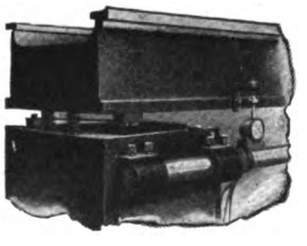
a scientific short-cut



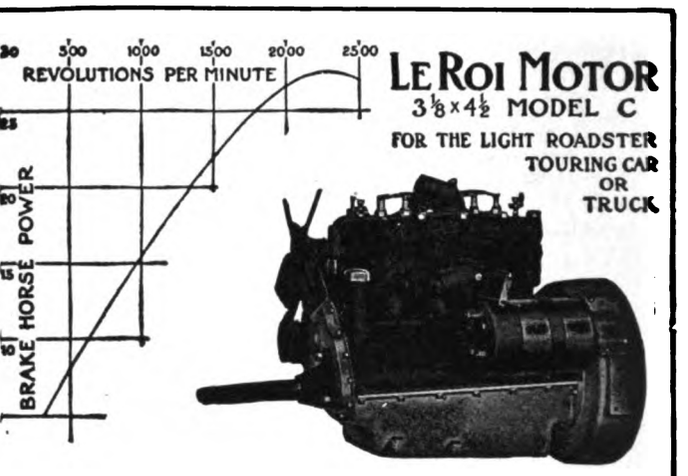
What the slide rule is to the engineer, the adding machine to the bookkeeper, the pyrometer to the metallurgist, the cutting-tool chart to the production manager—

Such is the Carwen Dynamic Balancing Machine to the process of balancing motor crankshafts.

It substitutes the precision of a machine for the fallibility of human brains—rapid measurement for tedious cut-and-try.

One Carwen machine will measure the running unbalance of 100 crankshafts in an 8-hour day. All the other work required to put the shafts in balance amounts to but 15 minutes per shaft.

With every day paid for in lives, the value of this scientific short-cut for airplane crankshafts is beyond estimation.



Supporting Springs and micrometer indicator at left end of bed, by which the slightest vibration due to running unbalance is shown.

District Representatives

The manufacturer of a well known automobile accessory will have several desirable District Agencies available very soon. Established business with jobbers and garages awaits a few high grade men with moderate capital and the ability to create and maintain aggressive selling organizations. Possible curtailment in automobile production means greater demand than ever. Our National advertising and liberal dealer helps will get this business for you. Address Box 13, Accessory Manufacturer, care of Motor World, Mallers Bldg., Chicago, Ill., for particulars.

Save Money Without Sacrificing Appearance

In this time of nation-wide economy, are you finding ways of cutting costs—and still retain quality? One item of saving—and it's no inconsiderable part of motor equipment either—is

GLASS

We have a mighty acceptable substitute for polished plate; and whether you use it on closed cars, windshields, clock faces, oil gauges or what-not, you will find it optically perfect. It looks well, too—and of course it's very moderately priced.

Write us your requirements, and let us tell you why this glass will serve your needs so well, why it costs less—and all about it.

It's YOUR Steel All The Way Through

Every order for *Agathon* Steel is "individualized" from the moment it enters our offices.

In other words, the USE to which YOU are going to put the steel is constantly in the minds of the men who create and handle it, from furnaces to shipping shed.

This is part of the *Agathon* system and is one of the features responsible for *Agathon* Quality.

AGATHON Steels will serve your purpose best.

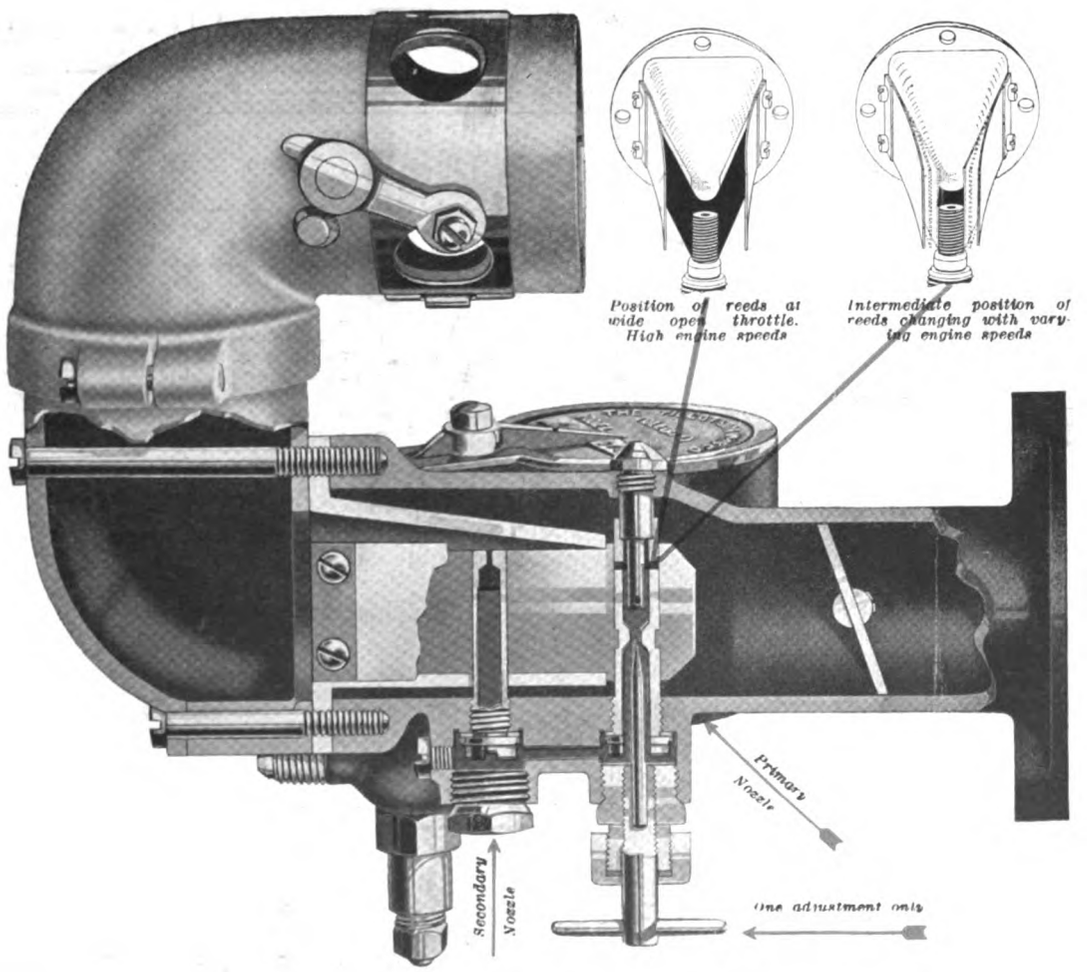
Tillotson

CARBURETOR

THE economy and efficiency of a carburetor depends upon its ability to produce a perfect power-giving mixture of gasoline and air at all times and at all engine speeds, ranging from the highest to the lowest.

Engineers who have made exhaustive tests of the Tillotson will vouch for its ability to produce such a mixture under all conditions of service.



Model "C" shown below is equipped with the same automatic air valve arrangement that features all Tillotson models and is also provided with both Primary and Secondary fuel supply nozzles.

The Primary nozzle furnishes fuel at *all* engine speeds but at the *slower* engine speeds is the *only* one in operation and is the *only* one provided with an adjustment.

The Secondary nozzle gives the added amount of fuel for *high* engine speeds and furnishes fuel at the *higher* engine speeds *only*.

Too rich a mixture or too lean a mixture is unknown to users of Tillotson Carburetors.

INSURE YOUR RADIATOR

THE only way you can be positive that your radiator won't freeze up this winter is to use a non-evaporating, anti-freeze preparation. The present high cost of alcohol—its low boiling point—and quick evaporation make it impractical. Besides, you are asked to conserve the supply of alcohol for use in explosives.

Does Not Evaporate

Johnson's Freeze-Proof does not evaporate so one application is sufficient for the whole winter unless the solution is weakened by leakage of the radiator or hose connection, through the overflow pipe, or by boiling over.

JOHNSON'S FREEZE-PROOF

Johnson's Freeze-Proof should be used wherever you wish to prevent water from freezing—in automobiles, gas engines, tractors, electro-lighting and heating plants, traction companies, etc. One box will prevent 3½ gallons of water from freezing at 5° below zero. For lower temperatures increase the portion of Freeze-Proof.

Absolutely Harmless

Johnson's Freeze-Proof contains no oil and does not interfere with the cooling system. It will not injure rubber, cloth, packing, or metal of any kind. It does not rust or corrode any metal. Johnson's Freeze-Proof is economical and easy to use and it raises the boiling point of water 12° to 25°.

Johnson's Freeze-Proof is put up in packages containing 6½ lbs. net which retail at $1.50 each in the U. S. A. One package will protect a Ford from freezing at 5° below zero. For larger cars use two packages to protect to 5° below zero, and three packages to protect to 20° below zero.

Write for our new booklet, entitled "Keep Your Car Young". — We will send it to you free and postpaid. — The information in this book will enable you to greatly improve the appearance and the performance of your car.

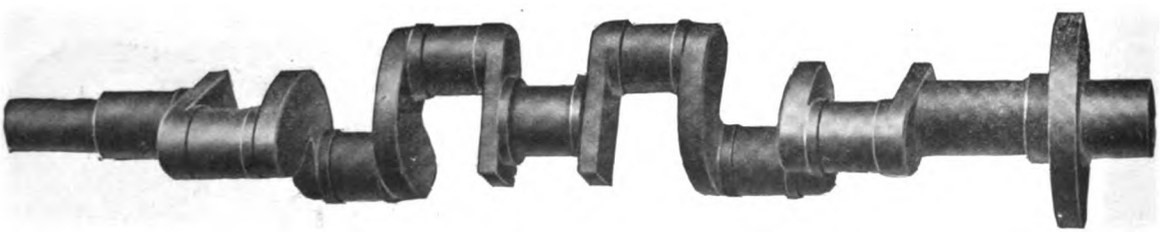
Guaranteed Forgings

-Put This Plant Behind Your Product



TRUCKS and ENGINES now building will be called upon for long, hard service. Both here and abroad the demand is for those that can survive the severest requirements. The "Survival of the Fittest" is being exemplified as never before. Trucks that stand up, engines that last and make good under these trying conditions, will make a reputation for themselves that will be very valuable after the war.

Get the Wyman-Gordon Guarantees on your Crankshafts and other forgings. It is a guarantee that means the fullest co-operation in working out your own particular problems in an efficient and economical manner. It covers Design, as well as material and workmanship, and guarantees you delivery of forgings that "stand up."

It will give you certainty of quality, and will save you time, money and worry.

Leading Manufacturers as well as the National and Allied Governments have availed themselves of our Special Facilities. We shall be glad to place the same facilities at your disposal.

"NORMA"
BALL BEARINGS
(Patented)

Service—that's what the buyer of a car or truck pays for. Its value to him lies in the measure of the service it renders. And this service must be a thing inherent throughout the machine—not merely in body, chassis or engine, but in every minute detail entering into their construction and equipment.

No part of the equipment is more vital than the magneto and lighting generator. And no part of these accessories is more vital than their bearings. Therefore—makers of high-grade, responsible magnetos and lighting generators have standardized on "NORMA" Precision Bearings.

VOL. XXXVIII NEW YORK—THURSDAY, JANUARY 31, 1918—CHICAGO No. 5

Chicago's War Show

Big Business Gathering

Leaders of Industry, Makers, Distributers and Dealers, on Hand in Greater Force Than Ever—Exhibit Carries Conviction of Its Institutional Value and Essential Need

CHICAGO, Jan. 29—Chicago's eighteenth annual automobile show and its first war show which opened Saturday afternoon is in full swing, and while the crowds are not so large as last year, the enthusiasm is equal to that of former years. The thousands of dealers and distributers are arriving and the show carries the conviction that war shows in America are not only institutional but a part of the war business that is not only essential but highly desirable.

The automobile and parts makers were not just satisfied with the New York show as a national show this year, describing it, as many do, as a show of glitter and attraction rather than a big, broad business enterprise; and with that verdict running through their minds, they have been waiting for the Chicago show to see if it would, under war conditions, swing into the channels of former years and demonstrate that it is the national and the essential show of the year and that big business conclave which the manufacturers want it to be.

Fuel Order Hurts Attendance

Those who have waited are not feeling disappointed and as the week progresses the feeling that Chicago is making good is bound to increase.

Closing the show on Monday, in accordance with the fuel order, set back the attendance a day over former years and dealers who would have been arriving on Monday were not registering until this morning. To-day each train has brought in large quotas of distributers and dealers. Nearly all large companies are convinced that all distributers and dealers of importance will be here as in former years, but that there will not be such a large representation of very small dealers as in former years.

These small dealers will scarcely be missed, and with the same representation of distributers and large dealers as last year there will be practically as complete representation from the country as in former years. Thus the show is already giving conclusive testimony that war shows are to be with us and that they will carry on the work of former exhibitions.

Cold Weather and Snow Interfere

The attendance has been good to-day and it was good on Saturday. If it falls quite below that of last year there is not any serious disappointment for Chicago is still in the midst of the longest spell of cold weather that it has had in the memory of many of the oldest citizens. In addition to having lived through a long spell of cold weather, the city is veritably snowbound.

Digitized by Google

A conservative estimate places 40 per cent of the city automobiles out of commission because of snow. Normally this percentage was in active use, but this year it is impossible to use them. Having 40 per cent of the cars out of commission is bound to cut down the city show attendance and this reduction is quite irrespective of anything connected with war activities and represents a condition entirely due to the snow.

The crowds surging through the Coliseum and Armory are more substantial than in former years. The crowd is much more largely made up of men. The men average somewhat older than formerly; there are fewer young men; in fact, their absence is quite conspicuous. There is also a perceptible absence of young girls and boys. The children with arms filled with catalogs are not present as in other years.

There are hundreds, and we hope thousands, of good inquiries for cars and while sales are few—the show is just in its second day—there is a better average of prospects than a year ago. The inquiries are not all for low-priced cars, but for the medium-priced machines as well. The percentage of inquiries is much larger in proportion to the attendance than it has been in former years, a condition which is quite natural.

Many Dealer Meetings

This week is listed up with dinners for dealers in about the same proportion as in former years, and owing to the show being closed on Monday the program of dealers' luncheons and dinners does not start until Wednesday noon, but continues regularly with every meal up to the climax, which will be the Society of Automotive Engineers' War Dinner on Friday evening at which 1500 diners are expected.

The program of manufacturers in general at these dinners is not known at this time but a spirit of optimism is generally expected to prevail. It is unfortunate that some enormous manufacturers' dinner had not been scheduled for Tuesday night, virtually the opening night of the show so far as dealers are concerned. There is in Chicago a hall capable of accommodating 3000 diners. With that number of dealers and three good speakers talking on the interpretation of present conditions there would be an opportunity for the manufacturers to do a united service to the dealers which cannot possibly be accomplished by the companies individually at their respective luncheons.

The makers have let a golden opportunity slip by of delivering that type of backbone lecture which the dealers are much in need of.

If one criticism might be lodged against the show, it is the fact that nothing has been done by the manufacturing industry to inject into the merchandising end a needed stimulant.

A chapter might be taken from the example of the Cleveland show last week in which they had a luncheon attended by over 400 dealers and at which Hugh Chalmers delivered a message which the dealers of Ohio were in need of. A great dealers' dinner by the manufacturers would have given a backbone argument to the dealer which he quite needs to-day.

Attitude Hard to Judge

It is too early to state just what is the mental attitude of dealers from all of the 48 States present, because some States are not yet represented.

It is too early in the show week to say just what is the attitude of the dealers. Some of them are a little glum and downhearted and need a mental stimulant. The good ones are generally very optimistic and the weak ones pessimistic.

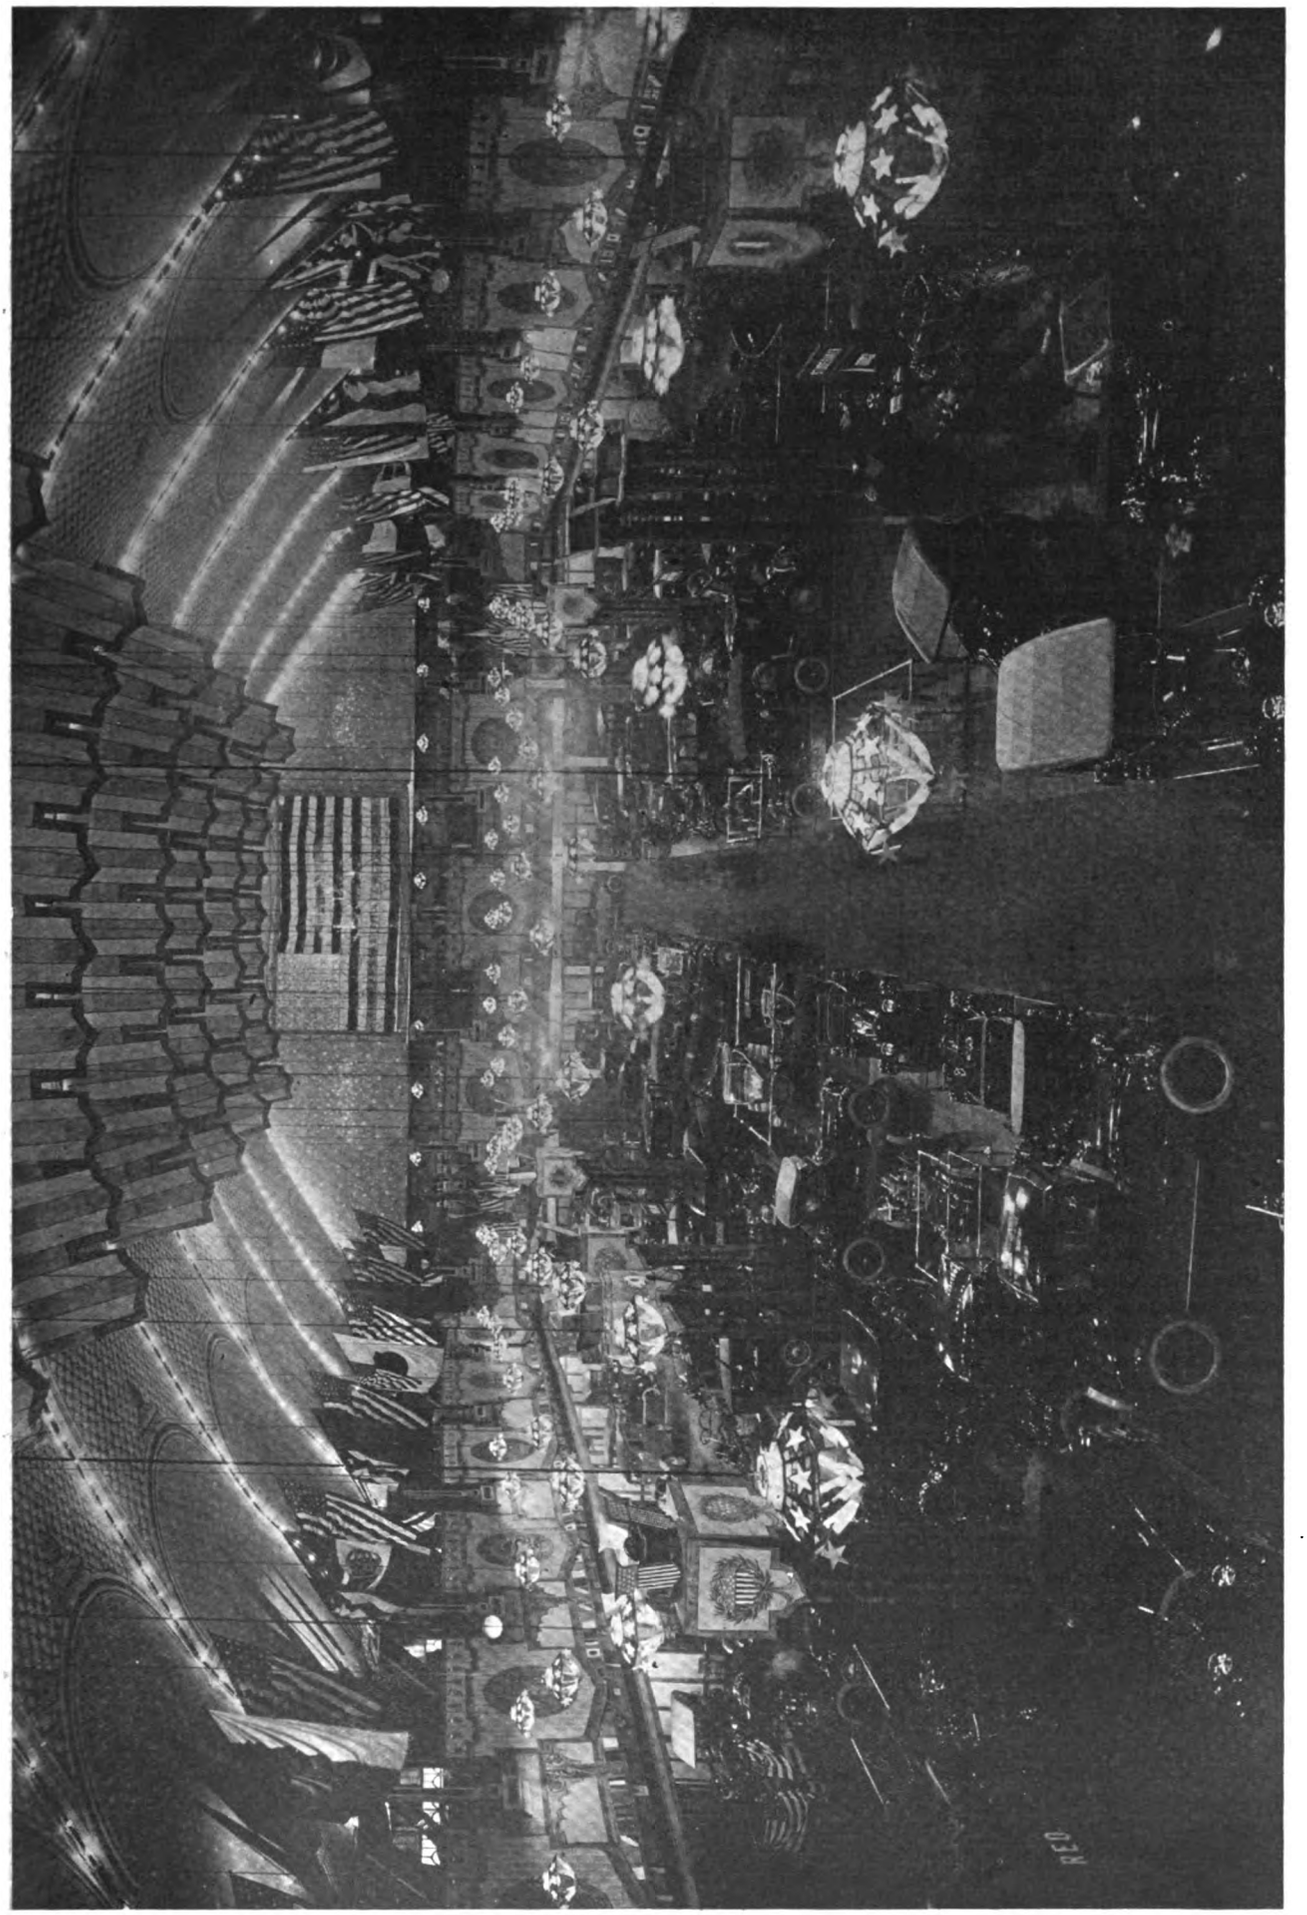
Never was it easier to classify the weak from the strong. The strong believe there is good business and are going after it with a will to get it. The weak talk about the bankers who are shortening up on credit, about the railroads and about conditions in general.

It is with these weak ones that the maker has to do his strong arm work this week. It is a case of need and we hope that those makers who are here to take charge of their dealers will deliver a message that will eclipse those of former years.

Meetings with dealers this year should be more than a mere jollification.

They must be business talks. They must analyze business and financial conditions.

They must get to the very nerve center.



Show is Proving Greatest of Business Exhibitions

INDICATIONS that there will be a shortage of automobiles soon, and that the price of used automobiles will increase are brought by every dealer arriving at the show here from the South. The South has had the greatest crop in its history, and the people are going to spend their money. The automobile as a means of transportation is the first thing that appeals to them. There are dealers arriving here from every town in many Southern States, and all bring the same story of an unprecedented demand for automobiles.

Negroes are buying $2,000 cars and sporting runabouts. Already the used-car trade in these States is growing by leaps and bounds. The possibility of not getting all of the new automobiles needed is right now influencing the used-car buyers. In the South it is not a question of how many automobiles can be sold but how many can be obtained to sell.

After really only one day of the show—that is Tuesday—the volume of business to be done and the amount of interest in the automobile and its parts was indicated last night, when one accessory maker declared that in one day—literally Tuesday afternoon—he had done more business than he did in the first three days of the New York Show. The Chicago Show is still maintaining its reputation as being the business show of the country, and is, in this first war year, distancing the New York show in this respect. Some of the big accessory jobbers in Chicago have their places of business crowded from morning until night. This is true not with one jobber only but with several.

Digitized by Google

Eighteenth Annual Automobile Exhibition in the Coliseum, Chicago

Digitized by Google

Never before has all Chicago taken on the show spirit as it has done this week. Chicago is passing through a veritable automotive industry week. While the exhibits in the Coliseum and Armory, figuratively speaking, represent the reason for the great week, still the entire city is given over to automotive ideas. Several of the largest department stores are staging automobile accessory exhibits, and they are being well patronized.

Every person engaged in business associated with the automotive industry is reaping the results of the great show week. With Chicago it is no longer an automobile show week but a great automotive industry week. It is too bad that there is not a tractor show running at the same time. The time is ripe for a motor cycle exposition. It is the best week for the motor boat interests to be displaying their wares.

Great Transportation Week

In fact, every branch of the automotive industry is profiting by this great transportation week, and by another year all of these several industries should be staging their individual exhibits and placing them in the greatest exhibition atmosphere that exists in the world.

For several years the two national shows, Chicago and New York, have been getting closer and closer together, so far as the actual exhibits are concerned, so that to-day the line of car exhibits is practically the same in one as in the other, Chicago perhaps having two or three local makes not seen at New York, and having perhaps one or two new body styles that were not ready for the New York show week. The days are past when Chicago had twenty-five or thirty exhibitors of automobiles that were not seen in New York.

Those were the days when Chicago staged a motor buggy show, and when literally scores of new concerns in the West made their début in the Coliseum. Now the ground covered by both shows is practically the same; the body styles seen at the two are practically the same; but still Chicago holds premiership in its show, even under war conditions, being the great gathering ground for dealers from the 48 States.

As to the display of accessory exhibits, Chicago is losing ground as compared with New York, the number of accessory exhibitors this year being less than that of a year ago, and many less than the number this year in Grand Central Palace, New York. Chicago should have the greatest accessory show of the two, and it is probable that the poor space for accessory exhibits is largely responsible for the fewer exhibitors. The accessory space rambles around the four sides of the Coliseum gallery, then it is squeezed into the four narrow balconies around the Armory, and its only free space is in the small second floor of the Coliseum annex and the basement.

New York has the ideal setting for the accessory maker on the upper floors of the Grand Central Palace with an elevator service from the ground floor to the top accessory floor, so that those who use the elevators must pass entirely through the accessory exhibit space. The accessory exhibitor has not as good a space in Chicago as he deserves, but there is nothing else for him.

Hotel Exhibits Well Populated

Each year finds the Chicago show dividing itself into two divisions, those exhibiting in the Coliseum and Armory and those opening offices in the Congress Hotel, where several floors are literally filled with offices of different makers of parts and accessories, who prefer to show their goods in the privacy of an office or in a hotel room rather than in a public exhibit space in the Coliseum. Each year this hotel show has gained in importance, so that this year one would be getting a quite incomplete conception of show week if he investigated only those exhibitors in the Coliseum and Armory. You must make the rounds of floors in the hotels before you discover all the developments in the different factories. Here in these rooms are being shown devices developed for Government use and which are being kept in secrecy but which after the war, or perhaps before that, will find their place in commercial lines.

Then, too, the Salon which is being held in the Congress Hotel in the large Elizabethan room on the first floor is attracting a great deal of attention and fits in wonderfully well with the big displays of parts throughout the hotel. In other hotels are many other parts makers who are showing some new developments, so that in a dozen places is the annual Automobile Show being staged in the Windy City. It is this widespread ramification of the show that leads to the conclusion that the Chicago show is to-day an institution of the automobile industry—an institution for the manufacturers, and should be an institution for the dealers.

More Than Mere Car Show

Unquestionably the time is not far distant when show week in Chicago will literally be automotive, instead of merely automobile. Literally speaking, it is more than an automobile show to-day, yet it is scarcely automotive. The time may not be far distant when a big farm tractor show will be held in the city the same week as the automobile show. The city has good facilities for such a show in the pavilion at the stock yards.

There is a reason why a national tractor show should be held in Chicago during the same week as the automobile show. There are many reasons for it. The dealers who have been selling automobiles are now selling tractors. The tractor will reach the farmer through the same channels that their automobile does. In the Middle West, or in all of our agricultural States, nearly 90 per cent of the automobiles go to the farmers. The farmer has established connections with the automobile dealer, and this dealer is the logical channel of tractor sales. The tractor maker is looking for agents, and he wants his show staged in a national atmosphere. Chicago offers such a setting.

Still a further reason for Chicago becoming a national show center, and holding an automotive show week. The thousands of parts makers who sell to the automobile maker, the truck maker, the tractor maker, the motorcycle maker and the airplane maker, can all meet these makers in this common center. The one week will give them the opportunity of exhibiting to all instead of two, one or two or three of them. The spark-plug maker is interested in all branches of the automotive industry, so is the maker of castings, the maker of forgings, the maker of stampings and the maker of bearings, electrical equipment and scores of other lines. There is no reason why Chicago, which has for years been such a generating center, should not carry forward to its fruitful completion this automotive show germ.

Sentiment for Big Dealer Show

Each year hears the rumor gaining around Chicago that the Coliseum show should be a big dealer affair managed by the dealers and distributers of Chicago and run for their special benefit. It is true the Chicago dealers are literally done out of a show which their fellow dealers in Boston, Minneapolis, St. Louis, Kansas City, and two dozen other cities stage to their own advantage and remuneration. Dealers feel that the time has arrived when the national show movement in Chicago should be handed over to them.

Digitized by Google

The argument goes to show how the Boston show, run by dealers, is a larger display than either New York or Chicago. It goes on to show that Minneapolis this year will have a larger exhibit than either New York or Chicago, so that the time has arrived when dealers' shows are excelling national shows in volume of exhibits. If the Chicago show were given over to the dealers, the show would be very little, if any, different, and the Chicago dealers, representing the largest distributing center in the world, would be given a participation in the industry which they have been denied for years but which is rightly theirs.

The present trend in the last few years of makers of parts preferring to show their devices in rooms in the Congress Hotel points to the fact that display spaces in the Coliseum and Armory are not entirely suited to these makers, and that, in a word, the public exhibit is really more for the retail trade than for the manufacturer. With the Chicago show in the hands of the Chicago dealers and distributers and with Chicago staging a complete automotive show week, the makers would be left free to carry on their business from the hotels and other places as they prefer to, and the public would have the same attention from the dealers which they are receiving to-day.

It now seems certain that many makers of parts and accessories consider the public exhibit space not entirely satisfactory for their needs. The exhibit space does not provide that seclusion which many of them desire. The big show is, so to speak, the billboard advertising for the great show week. It is the centerpiece of the week, in short, the reason for the automotive show week. The industry must get together, and Chicago show week has in years past demonstrated that this is the one suitable time of the year for such a rendezvous of transportation makers and merchandisers.

Several New Cars at Chicago Show

Deering Magnetic

DURING the week of the show the new Deering magnetic made its début at the Congress Hotel. This car is to be produced in four different types for the 1918 season, including a road car, seven-passenger, an all-season sedan, a four-passenger sport roadster and a coupe. However, it was impossible to get the last two ready in time for the show, and so only the seven-passenger road car and the sedan were exhibited. No definite announcement as to prices has yet been made, but it is understood that the seven-passenger road car will sell at $3,950. This will place it in a somewhat different price class from the Owen Magnetic, which sells at $5,300.

A six-cylinder engine is used, of the overhead valve type, the valves being inclosed and the cylinder heads removable. The engine was specially designed for use in this car by George P. Dorris, one of the pioneers of the American automobile industry. It has a bore of 4 in. and a stroke of 5 in., and though its S. A. E. rating is only 38 hp., actually it develops 70 hp. In order to eliminate all chance of whipping, both the crankshaft and the camshaft are supported in seven bearings. A hot-spot type of manifold is employed, which is said to be of such design that although it insures thorough vaporization of the fuel, it will not expand the air to such an extent as to excessively reduce the volumetric efficiency. The engine, of course, has been especially designed with a view to the use of the Entz magnetic transmission.

The five-passenger sedan, with two auxiliary chairs of the disappearing type, is finished in two-tone mole skin, with black fenders, wheels and running gear. The upholstery of mole skin velour mohair extends only to the window line, the interior above that point being painted in a harmonizing shade, and the flexible, bevel-edged roof is provided with a beamed ceiling to eliminate rumble. In summertime the glass may be dropped into the body and seat covers used to protect the interior against dust and rain.

Maibohm Shows New Six

THE Maibohm six-cylinder six-passenger sport phaeton is one of the few entirely new models revealed at the Chicago show. The exhibition model is finished in powder blue with khaki top. This new car is the product of the Maibohm Motors Co., Racine, Wis., which has hitherto specialized on a four-cylinder sport roadster.

The new Maibohm Six has a valve-in-head Falls engine of 3⅛-in. bore by 4¼-in. stroke, with detachable cylinder head. A Wyman-Gordon counterbalanced crankshaft, 2¼ in. in diameter, with three 2-inch bearings, is used. Valves are 1⅛ in. in diameter and lift 9/32 in. The valve adjustment is at the cylinder head and directly accessible. The Stewart vacuum tank is supported on brackets in an elevated position so that there is no interference with the adjustment of any of the valves. The engine is rated at 23.4 hp., but develops 40.6 hp. at 2290 r.p.m. Its maximum speed is 3510 r.p.m.

The equipment consists of a Wagner two-unit, six-volt starting and lighting system, Atwater Kent ignition, Willard battery, Stromberg carbureter, Perfex radiator for thermo-syphon cooling, Borg & Beck clutch and Mechanics three-speed transmission, the latter forming a unit with the power plant. By overhanging the levers of the transmission they are brought within easy reach of the driver. A worm and pinion speedometer drive is inclosed in the transmission case and drives the Stewart 60-mile speedometer. The storage battery and the adjusting turnbuckles on both brake rods are located directly under the front floor boards. The battery is thus easily removed from its steel cradle, and the large turnbuckles make brake adjustment a simple matter.

On the left-hand side of the engine are located the oil gage and filler, the electric generator driven through a universal joint type coupling and the ignition distributor, the latter an independent unit on the rear deck of the crankcase, this location permitting a simple wiring layout. Both manifolds are cast integral with the cylinder head, making for simplicity of pipe connections. An instrument board plate carries all necessary connections and is installed with four wood screws. Six bolts through the frame hold the body to the chassis.

Hotchkiss drive is used. The power is transmitted through two 4½-in. universal joints and a tubular propeller shaft. Both sets of brakes are lined with asbestos fabric and act on rear wheel drums, 12 by 2½ in., internally and externally. A Maxim silencer is fitted and the steering gear is of the Jacox, split-nut type. A 17-in. notched-grip hand wheel carries the spark and gas quadrant and horn button.

The rear axle is full floating, with 1⅛-in. shafts, a Brown-Lipe-Chapin differential and Hyatt roller bearings. Two Bock taper roller bearings are in the third member, which has an external adjuster. The gear ratio is 4.5 to 1. The front axle is a drop forging of 2-in. I-beam section.

All springs are semi-elliptic, the front ones being 36 by 1¾ in. and the rear ones 49 by 1¾ in. All three cross girders of the frame are straight. Wheels are artillery type with Stanweld rims. Houk wire wheels cost $100 extra for the set of five. The tire equipment is Goodyear, 32 by 3½ in. The wheelbase is 115 in., the road clearance a full 10½ in., and the complete car weighs 2375 lb. The price of both four-passenger and six-passenger touring models is $975 at the factory. Finish is optional with the purchaser.

The six-passenger job is long, low, narrow and rakish in appearance. The body does not project into or over the rear fenders, which extend a full 10 in. on each side. There are two folding auxiliary seats in the tonneau.

The khaki top is of Victoria shape. Gypsy curtains completely cover the top bow sockets, and have a round, bevel-

Digitized by Google

edge plate glass curtain window in each side. There is also an oval plate glass window in the rear.

Six Cylinder Comet an Illinois Product

THE Comet, which is made by the Comet Automobile Co., Decatur, Ill., is a six-cylinder car developing 50 hp. at approximately 2400 r.p.m. The cylinders are cast in block and surrounded entirely by waterjackets. Cylinder dimensions are 3½ by 5 in. Lubrication is by combination force feed and splash with individual constant level trough for each crank. Intake ports cast in the exhaust manifold provide for preheating the gas mixture before entering the cylinders. Cooling is by a centrifugal water pump with large cellular radiator and ample waterjacketing. A roller bearing fan with five double blades is used. The flywheel is inclosed in a bell-type housing.

Starting and lighting are by the Dyneto two-unit system with Bendix drive to the flywheel. Ignition is Delco. A dry-plate clutch is used, and the three-speed selective gearset is in unit with the engine. Two universals and a tubular propeller shaft take the drive to the rear axle.

The front axle is an I-beam type with Elliot knuckles. A three-quarter floating rear axle is fitted, the gear ratio of which is 4½ to 1. Hyatt and Bock bearings are used on the pinion shaft, differential and wheels. Brakes are internal and external on the rear hub drums. Semi-elliptic front springs, 2 by 36 in., and cantilever self-oiling rear springs, 2½ by 50 in., are used.

The frame is of pressed steel, heat-treated, with a kick-up over the rear axle. All cross members, gussets, hangers, etc., are hot-riveted. Wood wheels with 33 by 4-in. tires are fitted, while wire wheels are optional. Firestone demountable rims are stock. The wheelbase is 125 in., and a road clearance of 10½ in. is given. A 22-gal. gasoline tank is mounted under the frame in the rear with a sight gage and large end filler.

Auburn

ONE of the new cars at the show was the Auburn Sport Model, equipped with a six-cylinder engine and mounted on a 120-in. wheelbase. This car is an unusually roomy four-passenger model and has the front seats divided by a wide aisle. The upholstery is leather and done in the flat French pleat style. The body is of the straight line design with the windshield placed at quite a pronounced angle. The chassis follows the general Auburn construction with such features as semi-elliptic springs, unit power plant, etc.

One of the features on this car is the attention paid to details. For instance, there is a locker under the rear deck to which access is gained by removing part of the rear seat upholstery, which comes out in a rectangular block form. Thus it is possible to conveniently carry packages in this compartment. The price of this car is $1,395. To meet the demand of those who want extra large power and high speed the Auburn Sport Model is also built on a large chassis, with 131-in. wheelbase and 55-hp. engine. This model is priced $1,685. These cars are products of the Auburn Automobile Co., Auburn, Ind.

Hackett

THE Hackett Motor Car Co., Jackson, exhibited three models, all using the same chassis. There were a two-passenger roadster in olive green, five-passenger touring in brown, and collapsible sedan, finished in maroon. This concern also had on exhibition one of the new Guy rotary valve engines, with which the Hackett line is to be equipped later on. This engine incorporates some unique features. The valves are of the simple disk pattern, with only one surface in contact with the seat. For this reason also the valve is free to expand and contract without danger of binding, it is claimed.

The valve driving mechanism is by means of spur gears which are attached directly to the stems of the valve and driven by a small master gear. The latter drives the two middle gears attached to the two middle valves, and these in turn operate the outer cylinder valves by being in mesh with them. The disks which constitute the valves are cut with eight ports, which means there are four intakes and four exhausts per cylinder. There are only three working parts to each cylinder. The gears operate in a bath of oil and are noiseless. The valve driving mechanism operates ⅛ crankshaft speed, and, due to the rotating motion of the valves, the latter are said to be self-grinding, thus making them carbon proof. The top of this engine has an aluminum head plate, the removal of which exposes the valve.

The chassis has a 112-in. wheelbase and a unit powerplant. The engine is a four-cylinder, having a bore of 3¾ in. and stroke 4½ in. Hotchkiss drive is used, the torque being taken through long semi-elliptical springs. The gears in the rear axle are of the plain bevel type. The roadster and touring car sells for $985, while the all-season car or open sedan is priced at $1,165.

Elgin

THE Elgin Six Sedan exhibited by the Elgin Motor Car Corp., Chicago, is of the Springfield type, having two doors, one on each side, and constructed so that it can be entirely closed for winter or open for summer. The chassis is the same as used on previous models and incorporates such features as a unit powerplant, Borg & Beck dry plate clutch, Wagner lighting and starting system, etc. The steering wheel can be adjusted so as to bring it out of regular driving position, providing plenty of room for the driver in getting to and from his seat. The floor is covered with Brussels carpet, held in place by snap fasteners. There is an interior electric dome lamp. The car is finished in black with silver striping on the body and wheels. The price is $1,645.

Pan-American

THE Pan-American Motors Corp., Decatur, Ill., exhibited three cars and a chassis in the Greer Building. Beside the regular five-passenger touring car there was a four-passenger close-coupled car and a four-passenger sedan. All of these models use the same chassis, which is powered with a six-cylinder 3⅛ x 5 Pan-American Rutenber engine. The standard wheelbase is 120 in. Gasoline is served to a Rayfield carbureter by a Steward vacuum tank, drawing from a 20-gal. tank at the rear. The main tank has a large filler cap with gage and drain plug at the bottom.

The frame has a double kickup at the rear and is reinforced by four independent cross members, which with the rear engine support are said to eliminate all frame wearing, body squeaks and hood climbing. Springs are all semi-elliptic, with the rear 58 in. long, underslung and suspended directly under the frame. There are wick oiling devices for all spring shackle bolts and also for the steering knuckle pins. Drive is through a Borg & Beck clutch to a Warner gearset in unit with the engine.

Chalmers

A CAR which attracted unusual attention was the race-about exhibited by Chalmers Motor Co., Detroit. This car was a duplicate of the one in which Joe Dawson established a new 24-hr. record at Sheepshead Bay, N. Y., last fall. Essentially the chassis of this car is the same as used on all Chalmers models, with the exception that the engine is placed a little farther back. The body is aluminum and fashioned to reduce wind resistance. Only 25 of these cars are to be made.

Jordan

A NEW show model is the Jordan Suburban, which is really a larger edition of the Jordan Sport-Marine, but with seven-passenger capacity. It is mounted on the standard 127-in. wheelbase, but the body design is so worked out that a heavily raked steering column is used. The chassis is 2 in. lower than the standard Jordan chassis, accomplished by improved spring susupension, and the body is 3 to 4 in. lower. It is sold in two color options, namely, Liberty blue with black running gear and Brewster green with black running gear. As a complete seven-passenger job it sells at $2,375, this figure including complete equipment, consisting of 33 x 4½ Firestone cord tires, wood wheels, Burbank top, clock, tonneau light, traffic bumper, Macbeth lens and extra tire and rim. Production will begin Feb. 1.

Marine Engineers Discuss Standardization

Standardized Fittings and Construction of One-Design Vessels in Large Numbers Chief Topics at Show Week Meeting Under S. A. E. Auspices—A Series of Marine Standards Adopted

EVIDENTLY the motor-boat and shipbuilding industries are at a critical point in their respective histories. Heretofore all of the larger vessels, and most of the smaller ones, have been built individually to order—custom made, as it were—but owing to the urgent demand for various classes of vessels created by the war regular manufacturing methods have been introduced permitting of making the parts in different plants, often located at great distances apart, and merely assembling them in the yards. This is the main thought that was put forward at the motor-boat meeting of the S. A. E., held at the Automobile Club of America on Friday evening. The plan proved a complete success in manufacturing a lot of 550 submarine chasers for the British Government in 1915-16, and is now being applied also to the production of cargo ships.

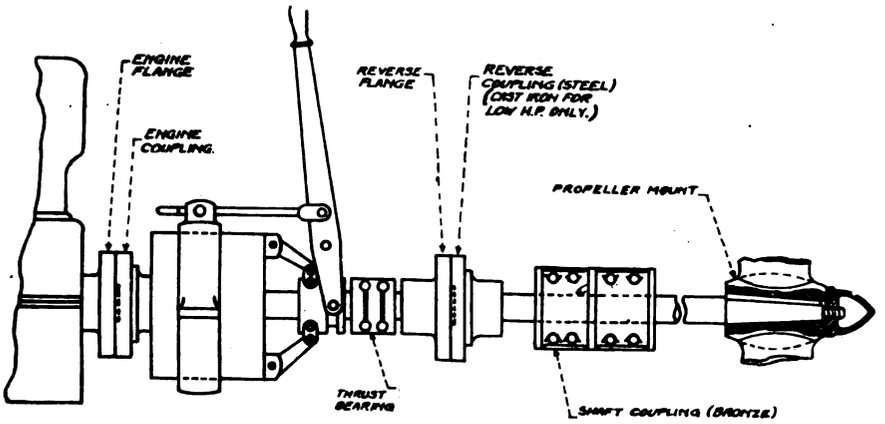
The meeting was preceded by a dinner, participated in by about 400 men, a goodly proportion of them naval militia officers. At the conclusion of the dinner the assembly proceeded to the large meeting room of the clubhouse, where four speakers enlightened them on subjects connected with ocean-carrying problems of the present day, and where they were entertained by the display of motion pictures of various automotive events.

Sutphen Talks on Cargo Ship Program

Although last on the program, the most important talk of the evening was that of Henry R. Sutphen, who gave an account of his experience in building 550 one-design submarine chasers for the British Admiralty, and of preparing to turn out one-design cargo steamers for the U. S. Government in large numbers. Mr. Sutphen said we had now had 1 year of standardization in marine work and had about finished beginning. There was a good deal of misconception of the real objects of standardization as carried on by the S. A. E. The object was not to absolutely standardize design but to harmonize design already made. Never before had the opportunity existed in the marine trade to carry through standardization to the extent that it was possible now. Formerly, boats were built instead of being manufactured, as the boat builders have to meet the wishes and whims of the public.

The first opportunity for real standardization came when the firm with which the speaker was connected received an order from the British naval authorities for 550 submarine chasers, all to be built according to the same plan. Some had said that the company would "blow up" in trying to do the job, but the order was completed ahead of time, in 488 days. This was in 1915-16, when the United States was still a neutral, and in order to comply with the laws of neutrality the boats had to be assembled in Canada. The plan was to so standardize the whole design that the assembling of the parts called for very little skill, and it was worthy of note that of the men employed in assembling work not 5 per cent could speak English, and not more than 2 per cent had ever been near a boatyard before.

Standardized Cargo Ships



At the present time the speaker's firm was building 150 steel cargo ships of 5000 tons each for the U. S. Government. These will be built also on standardized lines. It was at one time believed that to win the war it was necessary for us to build as quickly as possible 1000 wooden ships. However, standardization is not possible in wood construction to the same extent as in steel construction; consequently it was suggested to the Government early in the war to build steel ships rather than wooden ships. The question then arose where to get the steel, as the U. S. capacity for producing ship plate was limited. It was then decided to develop an entirely new design of cargo vessel, employing structural shapes, and after the design was completed it was passed by Lloyd's as A1; that is, equal to the very highest type of construction.

To secure the necessary large organization the company turned to the trades that it believed would be idle as a result of the outbreak of the war, including the building trades, the bridge builders and tank manufacturers. Contracts for parts were let with, and parts are now being manufactured in forty-six different shops scattered all over the country. So far, four keels of 5000-ton ships have been laid, and it is intended to build 150. Every worker, not only in the yards but also in the different structural shops, knows that he is working on parts to go into ships, and takes an interest in his work. Fully 90 per cent of the work in building the ships will be done in the shops throughout the country.

Turbines and Water-Tube Boilers

When it came to the selection of the machinery the use of turbines instead of reciprocating engines was decided upon, although turbines had never been used before in cargo ships. The reason for selecting the turbine was that it is a better manufacturing proposition than the reciprocating engine, and for the same reason the water-tube boiler was given preference over the tubular boiler.

Digitized by Google

Showing standard couplings and propeller mount assembled

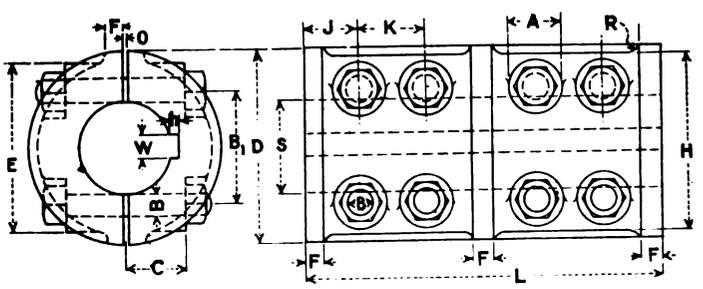
Arrangements had been made which would result in the machinery being turned out quicker than the hulls. Altogether, 225,000 hp. would be required. An ultimate capacity of one 5000-ton ship every 2 days was being aimed at in the Newark yards, where twenty-eight ways have been established so far.

Man power, Mr. Sutphen said, was one of the vital things in the war, and it was a most fortunate thing that at the Newark yards each gang took great pride in its way and made every effort to excel the other gangs. The company would employ anybody who stood on two feet and was healthy, and would try him in six different departments before letting him go as unfit. They would teach him to drive rivets tight and to calk joints—just one detail—and it was remarkable the efficiency which was developed in a short time.

Some of the old iron shipbuilders had questioned the practicability of the new method, and all naturally wondered how it would work out—how the parts built in forty-six different shops would come through in the proper order and then fit together. After laying the first keel the plates began to come in, and they fitted together to a hair's breadth, although these plates had been cut in a shop 1000 miles distant from where the keels had been made.

Hearty Co-operation

In addition to the Newark yards, two other yards have been established and will soon be in full swing. The public realized we must have the ships, and the spirit which had come over the country was most encouraging to him and his associates. As their representatives were sent to different large manufacturers throughout the country they met with a cordial reception everywhere, and the general tone of the officials of these companies in negotiating with the representatives was: "The best that we have you can have."



All of the talks were more or less informal, and there was no discussion. Later in the evening a number of reels of moving pictures were run off showing tests of the Class B motor truck and its engine, aviation activities behind the fighting front in France, activities in the U. S. Navy, and scenes in the building and testing of submarine chasers.

Irwin Chase, talking on standardization of motor-boat construction, said that prior to the building of 550 80-ft. submarine chasers it had always been considered impossible to standardize boats or their fittings. The order for this fleet of chasers made possible the first serious attempt at standardization.

In consequence of this work it is considered economical to standardize the shape of the hull and the lines as well as the various fittings. The advantage of standardizing lines was well brought out in these chasers. For example, it was not found necessary to make extensive tests with models, because of the known characteristics of the lines chosen. However, several models were towed as a check. Furthermore, the use of standardized lines required no experimenting to determine the power needed for certain speeds.

The standardization has been carried with great success even into the propeller field, propellers being designed of standardized size, shape, and section of blade. Although it is not possible to standardize fittings which shall be applicable to all boats, some fittings can be so standardized that they may be made to perform a number of functions. For example, shaft struts have been standardized so that it is no longer necessary to have lefts and rights.

The particular advantage of standardization becomes most apparent where a large number of boats are fabri-

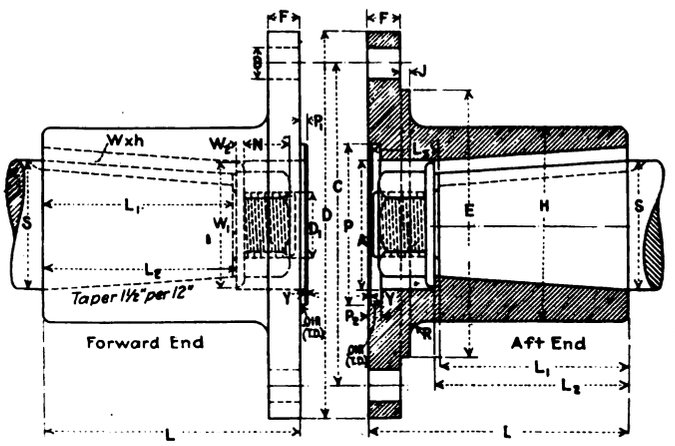
cated in one place and the assembly work is carried on elsewhere. Such manufacturing methods require interchangeability, not only of the fittings but of the hull and all its various parts, including the frames, keels, planking and trim.

There is one important disadvantage connected with standardization, viz., the danger of slight mistakes, which, in the case of quantity production, quite obviously are multiplied by the number of boats built. Furthermore, with standardization carried to a high degree, it is impossible to make slight changes in the middle of a job.

Interchangeability has been found of tremendous advantage with these 550 chasers in service abroad. It has facilitated replacement of parts and greatly simplified repair work.



The greatest need at the present moment, from the viewpoint of the designer, is for standard specifications of materials. At present much time is consumed and a handicap imposed on designers by the necessity for drawing up individual specfications for many of the materials used.

W. S. Howard, a member of the marine division of the S. A. E. Standards Committee, spoke on "Standards." The Division had a meeting on Friday afternoon, at which the standardization work so far accomplished by the S. A. E. in this particular branch of the automotive industry was reviewed. He pointed out the difference between specialization and standardization, which is often lost sight of. Reducing the number of models turned out by a manufacturer is not standardization, but rather specialization.

How Standardization Began

The advantage of standardization to an industry, Mr. Howard said, was clearly shown by the progress made by the automobile industry. Standardization began with screw threads. Early in the history of the automobile it was found that the old U. S. S. standard screw thread was unsuitable, and that finer pitches were required. Progressive manufacturers began to develop their own fine pitches. This led to chaos, and so an attempt was made, and successfully carried through, to develop a new fine-thread screw standard, known as the A. L. A. M. standard. This was practically the beginning of the standardization work which was carried on first by the A. L. A. M. Mechanical Branch and then by the S. A. E.

About 2 years ago last November Mr. Howard said he sent a circular letter to a large number of engine and boat manufacturers urging them to organize for the purpose of standardization. A meeting was finally arranged to be held at the time of the motor-boat show, with the co-operation of the National Engine and Boat Manufacturers' Association. Among the representatives of firms of the latter association present at the meeting were Messrs. Sutphen, Van Blerck, Clayton, Milbrath, Riotti, Tuttle and Howard. Another meeting was held early in the season, and those in attendance remained in session from 10 a. m. to 4 p. m. One of the first things that was done was to go over the standards which had been established by the S. A. E. for automobile work and pick out those which were suitable for marine practice. In this way a list of thirty-odd standards were selected. Plans were also laid for the future work of the division, it being decided to consider first of all the subjects of batteries, shaft couplings, en-

gine couplings, reverse couplings and propeller mounts.

Mr. Howard then outlined the underlying thoughts which led to the formulation of the standards herewith reproduced, which were accepted by the Standards Committee at its last meeting. One difficulty that was encountered was due to the fact that some of the smaller boat builders do not appear to be quite ready for standardization. In the case of propeller shafts, for instance, it has been their custom to order the shafts a little long and then to cut them off to suit. Therefore, tapered seats cannot be turned on the shaft at the factory, and inasmuch as the boat builders have not the necessary equipment for turning such tapered seats there has been some opposition to the adoption of this standard. This difficulty was met by making a straight seat optional. Mr. Howard further pointed out that all the standards so far adopted had been submitted to interested Government departments, and had met with their full approval.

The division next will take up the subjects of batteries and engine supporting arms.

A. P. Lundin, who has been devoting his efforts for many years to the development of lifeboats, was slated to talk on the subject of fitting power boats to transports. Mr. Lundin said that the average man did not realize the great difficulties connected with the problem of transporting our army and all the necessary supplies abroad. Most people regarded the design of such boats as a very simple matter, chiefly "because you really never intend to use them." He started out some years ago with a model of a new type of lifeboat which he showed to shipbuilders in different parts of the country. They were all very much interested, but when they learned that the cost of this boat would be from three to four times as much as the equipment they were then providing their interest lagged. Looking at the financial side of the matter, Mr. Lundin wanted to know whether any one in the audience had ever heard of a builder of lifeboats, either in this country or abroad, who had become rich. It was his positive conviction that there were none. He said that the subject of lifeboats and life rafts had not received the consideration they deserved. Even among seafaring men there were as many ideas regarding the proper construction of lifeboats as there were stars in the sky. Besides the construction of the boat there is the problem of the proper placing on the ship and of properly daviting them. When he first went to sea he remembered an instance where it took a whole day to get a single boat into the water, it being frozen tight and the davits too short. Just to show how little attention was being given to the subject, he mentioned that some years ago, when a law was passed that all ships should have sufficient lifeboats to accommodate everybody on board, pontoon boats were adopted, made up of metal tanks and canvas, but they were entirely too flimsy. In his construction another boat was placed on top of a pontoon. It was only necessary to launch the other boat and to release the pontoon or raft, which, if the ship sank, would float away. One of the difficulties of the ordinary lifeboat is that it capsizes easily, and if it is then righted again it is half full of water, which makes it very unstable.

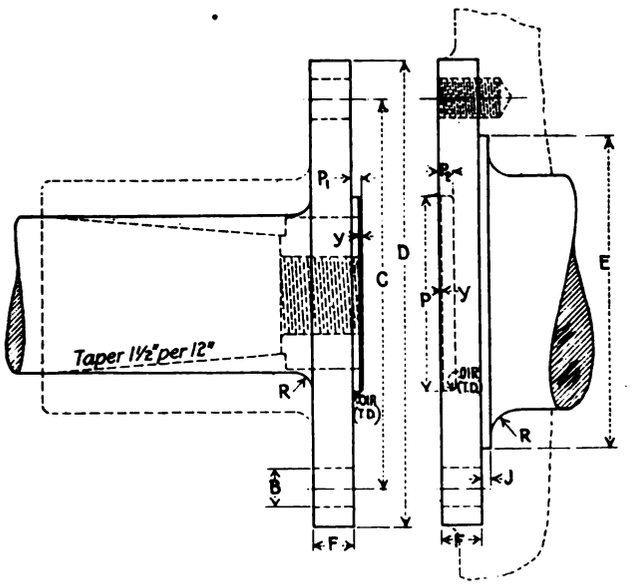
Motor Life Boats



In Mr. Lundin's opinion it is strange that motor-propelled lifeboats did not come into general use long ago. His only explanation was that men in general were slow to adopt innovations. In his opinion a motor-propelled lifeboat was as far ahead of the ordinary lifeboat as a motor truck is ahead of a

Dimensions given in inches. *Threads, U. S. forms.
NOTE—The male flange, when integral with engine shaft, is shown in full lines in the cut. When separate, the shaft taper and dimensions are the same as for Steel Reverse Couplings of the corresponding size.
*The female flange, when designed as shown by full lines in cut, will have drilled bolt holes. When designed integral with reverse parts as shown by dotted lines, they will be drilled and tapped for S. A. E. Standard bolts.
(T. D.) Tooling dimensions.

Engine Coupling (Steel)

Propeller Mount

forty to sixty people, and double that number in emergency. Engines should be of the heavy-duty type, of about 24 hp., and the tankage should be such as to provide a cruising radius of 200-300 miles at 6 to 7 m.p.h. Speed is not an important consideration, but substantial construction is. The engine should be encased in a steel trunk, so as to be fully protected from the water. Such lifeboats would cost much more than is now spent for the purpose, but think of the advantage of making adequate provision for saving the lives of the most valuable people we have—captains, officers, sailors and soldiers. He had observed people having relatives in the Army and had noted that many were much more concerned regarding the dangers afloat than the dangers of the trenches.

wheelbarrow. A real lifeboat ought to be built on the principle of Noah's ark. If the ship sinks, all you have to do is to get into the ark and close the door behind you. Noah, unfortunately, was unable to secure a motor for his ark, otherwise he probably would not have been hung up on the mountain peak where he landed.

Quite a number of motor lifeboats have been built for the transport fleet. In Mr. Lundin's opinion not only every transport steamer, but also every cargo ship, should have at least one motor lifeboat, especially under present conditions of navigation on the Atlantic. If this practice were followed not only would more people be safe when a ship sank, but the danger of getting lost on the ocean would be greatly reduced. With one motor lifeboat it would be much easier to keep the rest of the boats together, and also sufficient provisions could be carried for the whole crew. Also if any one got sick he could be taken into the motor lifeboat, where he would be better protected from the elements. For cargo boats, Mr. Lundin recommends lifeboats 28 to 30 ft. in length, with a capacity for carrying

Specifications for Class B Chassis Assemblies

1. **Trucks**—All trucks furnished under these specifications must be assembled complete by the chassis builder, to drawings and parts list furnished by the Motor Transport Section, O. Q. M. G. This will include bodies, tires, tools, spare parts and all equipment specified in parts list. All assembled units must bear the approval mark of the inspector before it is mounted in place.

2. **Front Axle**—Spring seats must be properly centered on axles, and all spring leaves must be in proper alignment. Spring clips must be tight. All spring bolts must be securely locked to prevent them from turning in the spring shackles, and must be lubricated before being set. All nuts must be drawn up tight and locked as specified by drawing. All rebound clips must be in place. Front springs must be assembled with long end to the rear.

3. Wheel bearings must be greased and kept covered until ready to mount wheels.

4. **Rear Axle**—The spring pins and bolts must be well lubricated during assembly and all nuts locked as per drawing. Spring clips must be tight. It is important that the springs be properly seated on the axle and rebound clips must be in place.

5. Housing shall contain the proper amount of lubricant and not leak at any place. Hub bolts shall be drawn tight.

6. **Engine.**—All bolts holding engine to frame must be tight and nuts locked as per drawing. Gasoline line and connections are to be free from all leaks. All wiring connections must be tight to insure proper contact. Spark control rods are to be adjusted and of such length that the full advance and retard of spark can be obtained by the lever on the steering column. All connections are to be oiled. Throttle control rods must be adjusted so that the full throttle opening may be obtained by both hand and foot throttle. The foot accelerator pedal must be far enough adjusted to give the full opening of throttle. All control rods must operate freely.

7. Intake manifold gaskets shall not leak and must be shellaced in place. All manifold nuts must be tight.

8. Valve tappets must be set to standard openings: Inlet, .003 to .006; exhaust, .005 to .008.

9. No oil leaks will be permitted in any part of the engine. The crank case shall be thoroughly inspected for oil leaks after road test while engine is running.

10. The radiator and water connections must not leak after road test with the engine running.

11. **Clutch Mounting**—The clutch must engage gently but shall not slip under full load. Adjusting nuts and springs must be tight and locked. Clutch and foot-brake pedals must be in center of floorboard slots. Pedal shaft is not to bind and all connecting link pins are to be a proper fit. All connections and bushings are to be lubricated. The front propeller shaft must run true between centers and be properly lubricated.

12. Particular care must be taken in the assembling of annular bearings that the pressing force is not transmitted through the balls nor races injured.

13. **Transmission**—Transmission must be in proper alignment. Transmission case shall not be damaged or strained by assembling. All bolts holding transmission to frame must be tight with nuts locked as per drawing.

14. Shifting rods must be properly connected and pins must be cottered and oiled. The transmission must contain the proper amount of lubricant and gears are to shift easily. The case shall not leak at any point, with special attention to glands.

15. **Drive Shaft**—Drive shaft must run true between centers. Universal joints must be properly lubricated.

16. **Brakes and Brake Rods**—All yoke pins must be lubricated when assembled and must be cottered. Lock nuts at turnbuckles must be tight. Rods must have the proper length of thread for adjustment. All equalizer bars must work properly and all pin connections free. Brake bands must be concentric with brake drum. Brake lining must have a good surface and touch drum at all points. Lining must not be ruffed up when wheels are mounted. All linkage must be well lubricated in order to have free action and prevent any dragging of brakes. Brake equalizer must be adjusted properly. Foot-brake pedal must be .. inches from dash when wheels are locked and .. inches when brake is off. Hand-brake lever must pull .. notches when wheels are locked.

17. **Wheels**—All wheel bearings must be loose enough to allow wheel to revolve freely, but must be tight enough to prevent any wabbling or side motion. Bearings and hubs must be packed with specified grease. Hub caps must be tight. Front wheel caps must be packed with grease. Bolts in driving flange of rear wheel must be tight with nuts locked.

18. **Radiator**—The radiator must be perpendicular to the frame at proper distance from dash line. Fan must clear radiator at all points. All water connections must be free from leaks with hose clamps tight and in place. Brace rod from dash to radiator and radiator hold down bolts must be secure and properly locked.

19. The radiator guard must be perpendicular to frame at the proper distance from radiator with all bolts tight.

20. **Dash**—The dash must be set at the dash line perpendicular to frame. All bolts must be tight and locked as specified.

21. Side lamps must be securely fastened to dash, completely connected and in operating condition.

22. Floorboards must be properly fitted to dash so that all openings come in the proper place.

23. **Seat**—The seat must be securely fastened to frame so that it does not interfere with the operation of any part.

24. **Hood**—The hood must be a good fit at both dash and radiator. Hood clamps must be in the proper place and shall grip hood securely to prevent rattling.

25. **Steering Gear**—All steering post bolts must be tight and dash brace must clamp and hold it securely. All steering connections must be lubricated during assembly and securely fastened and locked.

26. Front wheels must be lined up and have the same amount of throw each way. Steering pivots must be tight fit and properly lubricated. Steering wheel must be securely fastened to column. Steering arms shall not interfere with axle at any point. All connections must be packed in grease and covered by leather boots.

27. **Fuel Tank**—The tank straps must be very tight to insure tank against any vibration. Tank must fit dash properly and must not leak.

28. **Bumper, Tow Hooks, Etc.**—Bumpers must be in place with springs at proper compression. All nuts must be locked.

29. Tow hooks must be tight with nuts locked.

30. Fenders must be free from vibration and tightly bolted in place.

31. **Electrical Equipment**—All connections must be properly made and all contacts free from dust. Wiring shall be made in such a manner as to make a short circuit impossible.

32. The battery must be securely fastened to its support and filled with the proper amount of electrolyte of the proper gravity.

33. Ammeter on dash must show 7 to 8 ampere charge.

34. The lighting and ignition switch must operate properly.

35. Dash lights must be properly connected and operate properly.

36. Tail light must be securely fastened to bracket and operate properly.

37. **Muffler and Exhaust Pipe**—The muffler must be securely fastened to frame by brackets.

38. Exhaust pipe joints at muffler and

The Technical History of the Airplane*

Three Classes of Flying Machines Possible, but the Airplane the Only One Which Has Reached a Practical State—How the Various Elements of the Airplane Have Been Gradually Developed

By Capt. F. M. Green

THE history and development of mechanical flight may be confined almost entirely to the present century. In the last century some success had been achieved in gliding flight, model aeroplanes had been made and flown, and at least two man-carrying aeroplanes had actually left the ground, but it was not until the year 1903 that the Wright Bros., having ended a painstaking research in gliding flight, earned for themselves the honor of being the first men to fly.

Directly the success of the Wright Bros. became known, or rather when people began to believe that what the Wright Bros. claimed was actually true, the development of flying became rapid in the extreme.

Directly mechanical flight was possible, full scale experiments were carried out, often at the risk of the life of the experimenter, and the more obvious problems became apparent. In the short space of 14 years our scientific knowledge of aeronautics compares very favorably with the world-old science of navigation of the sea.

It is the intention of this paper to discuss the progress that has been made in dynamic flight and to consider the chief factors that have made this progress possible. An attempt will be made to state in a general way the standard of development as it exists to-day, and to consider the possible direction of progress in the future.

Definition

The flying machine is an apparatus in which an arrangement of surfaces is moved in such a way that the reaction of the air provides a vertical component of the force on the surfaces equal to the weight of the apparatus. An aeroplane, as we know it, has its supporting surfaces fixed relative to itself and is driven forward by the reaction of one or more airscrews.

Besides an aeroplane, two other sorts of flying machines have offered possibilities to the inventor. One is known as the Helicopter, in which the lifting surfaces are revolved in a horizontal plane. The second is called an Ornithopter, and in this the supporting surfaces are moved in a way to imitate a bird flapping its wings. Although both these types are conceivably possible, their usefulness and practicability appear doubtful and it is only proposed in this paper to consider the aeroplane as we know it.

Aeroplane Performance

Nowadays we make careful measurements of the characteristics of each new aeroplane at various heights, and the word "performance" is used to refer to the speed, rate of climb, and load carried. A good performance is one of the important essentials of usefulness of an aeroplane, and we will now consider the factors that have enabled us to improve so much on the early aeroplanes.

There are four main factors that govern the performance of an aeroplane. They are: I. The wing surface that supports the weight. II. The total weight supported in flight. III. The resistance of the aeroplane to forward motion. IV. The thrust available from the airscrew or airscrews.

These factors are very intimately connected, and each in turn will be considered, its effects discussed, and the possibility of improvement outlined.

*Lecture delivered before the Aeronautical Society of Great Britain.

As to the wings, it is necessary to know how to express the value of any particular arrangement of surfaces. The result at which to aim is to obtain the maximum vertical reaction or lift for the minimum horizontal reaction or drag. The term lift-drag ratio is, therefore, a measure of the effectiveness of a plane. Another attribute is, however, desirable, viz., that the lift per square foot of plane shall be high, so that as little surface as possible need be used for a given minimum speed of flight.

Planes vary in curve, plan form, and arrangement and number of surfaces. The designer will vary these factors according to the sort of aeroplane he wishes to make.

Wing Section

The Wright Bros. did not know if they would be able to fly at all. They chose deeply cambered wing sections so that the maximum lift could be obtained at the minimum speed. The lift-drag ratio of their planes was probably about 12 to 1, very much better than still earlier experimenters could obtain with flat planes. Present-day wing sections enable us to get a lift-drag ratio of 17 to 18, while model tests have shown as good a ratio as 23.

For a given minimum speed we need more surface to support a given weight than with a more cambered plane with a worse lift-drag ratio. It would be an advantage if we could vary the camber of a plane to suit the speed, and many attempts to do this on an aeroplane in flight have been made. Unfortunately, apart from increased complication, the increased weight is likely to cause greater loss than gain.

Shortly before the war an experimental aeroplane was made at the Royal Aircraft Factory, which was fitted with wing flaps nearly the whole length of the plane. These flaps could either be turned down for low speed, or up for high speed, or they could be used differentially for balancing. It was, in fact, rather a crude way of varying camber. Although it achieved the distinction of being possibly the fastest aeroplane of the day, it was eventually considered that the extra weight and complication did not justify the device.

From many considerations it appears that much improvement in lift-drag ratio is unlikely, but when the speed of aeroplanes becomes very much greater than it is to-day, it is quite possible that some device for changing the section of a plane during flight will be found necessary to obtain a reasonably slow landing speed.

Plan Form

Planes are generally made nearly rectangular in plan but with the ends more or less rounded. The ratio of span to chord is called aspect ratio and the higher this is made the better will be the lift-drag ratio. Here, again, it is necessary to compromise, as the bigger the span of the aeroplane the heavier will be the wings, the greater the resistance of the necessary bracing and the rapidity of the maneuvering of the whole aeroplane will be decreased. From practical consideration, therefore, the aspect ratio of an aeroplane is generally from 5 to 8; recently some large aeroplanes have gone considerably beyond this figure, but it is very doubtful if anything has been gained.

Little is known as to the effect of using planes other than roughly rectangular, but it is not very likely that much improvement will be found with planes of other shapes.

The original aeroplane of the Wright Bros. was a biplane,

Digitized by Google

consisting of two planes separated by about the width of the chord. Shortly after, monoplanes, triplanes and quadruplanes were made and flown. It is fairly certain that the most efficient plane is the monoplane, for there is no possibility of interference of the planes as there is on the multiplane. A biplane, however, is probably only a little worse than the monoplane, while a triplane is a little worse than a biplane and so on. Structurally, the biplane is very much easier to make than the monoplane and, owing to this, the biplane construction has been almost universally adopted. Triplanes and quadruplanes have not had very much success, although it is quite possible that for very large aeroplanes the advantages gained in construction may outweigh the disadvantages of their somewhat low effectiveness.

From time to time suggestions have also been made that the amount of wing surfaces should be varied. This again is a complicated thing to do, and with modern wing sections there is practically never any gain in reducing wing surface; in fact, most aeroplanes would fly faster and not slower by having more surface if such surface could be introduced without extra weight or external resistance. This applies particularly to flying at heights.

Weight

The total weight that is carried on an aeroplane is obviously all-important, and it will, therefore, be useful to see what prospects we have of decreasing the weight of aeroplanes of any given type. We will divide the aeroplane into the following components: (1) Useful load; (2) motor unit; (3) fuel, oil and tanks; (4) remainder, being aeroplane parts proper.

For the purpose of general analysis it is assumed that the motors consume the same amount of gasoline per b.hp. per hour and the figure 0.7 lb. per hp. hour is sufficiently accurate to cover the weight of fuel, oil, tanks and pipes. There are, of course, engines which do better than this, and many which do considerably worse. It is, however, a fairly good average.

Analyzing a number of aeroplanes that have been used under active service conditions, it has been found that, apart from the useful load, the motor unit, and the gasoline, oil and tanks—the remainder representing the aeroplane proper—is very nearly one-third of the whole weight—32 per cent being rather nearer. This weight includes the wing structure complete, the body complete with its fairing, floor, seats, controls, instruments, etc., the tail plane, elevator, rudder and fin, and the landing gear and tail skid. This weight is on the average made up as follows:

	Percentage of aeroplane parts, Per cent	Of total weight, Per cent
Wing structure complete	41	13
Body complete	41	13
Tail plane, elevator, rudder and fin	6	2
Landing gear	12	4

If we take 32 per cent as the weight of the aeroplane proper we have the balance of 68 per cent to divide up among the motor unit and its fuel and the useful load.

We have now only to decide what percentage of useful load we shall carry, and for what time it is to be carried, and we can find at once the weight per horsepower of the complete machine. We shall see that from the figure of pounds per horsepower of the loaded aeroplane we can get a very good idea of its probable performance.

Possibilities of Reduction of Weight

The weights of the aeroplane parts have now been fined down to a considerable extent and except for the use of the newer materials, progress in saving weight is not likely to be very pronounced. Undoubtedly as time goes on we shall learn to make equally strong structures for less weight and the development of aluminum alloys and pressed metal construction may help to a marked extent. At the present moment wood is used very largely in the construction of both the bodies and wings. To a great extent this is due to war urgency, and no doubt aeroplanes of the future will be made of more durable materials.

The chief particular in which it is probable that weight will be reduced is in the weight per horsepower of the motor. Although progress in this respect has been remarkable, it is probable that we have not nearly reached the limit of weight in internal-combustion motors. At the present day the complete motor unit, i.e., the motor itself, the airscrew, water and radiator if water-cooled, exhaust pipes, and so on, weighs generally from 3 to 4 lb. per horsepower. Certain very light motors have been made in which the weight is very little more than 2 lb. per horsepower. It is quite conceivable that in the next few years motor units of 1½ lb. per horsepower will be available, and in all possibility with the improvement in material will enable us to make motor units weighing not more than 1 lb. per horsepower in the more distant future.

With regard to fuel consumption the best gasoline motors have a brake thermal efficiency of about 30 per cent. It may be this will be improved, and here again saving of weight may be effected.

The only motive power used to-day is supplied by internal-combustion engines. Some day no doubt a lighter form of motive power will be developed, and it is in this respect that the most startling progress may be expected.

Resistance of the Aeroplane to Forward Movement

The resistance of the aeroplane is made up of two factors. The first is the resistance of the main planes. The second is made up of the resistance of the body, the struts, wires and fittings of the wings, the landing gear, tail plane, rudder and so forth. These can all be grouped together under the general term of body resistance. It is in respect to the reduction of this resistance more than anything else that the modern-day aeroplane owes its superiority over that of the original Wright machine.

The first man who seems to have understood the importance of reduction of resistance was the late Edouard Nieuport, who in 1909 produced an aeroplane with a very fat body which almost completely inclosed the pilot and succeeded in making a big improvement in speed on an aeroplane of comparative small power. Since that day all modern aeroplanes have been inclosed as completely as the requirements of the pilot's view allows.

Details of Resistance

The resistance of the external parts of the aeroplane has now been fined down to a considerable extent. The various components of the aeroplane will generally be found to have the following proportional resistances:

	Per cent
Body	62
Landing gear	16
Tail plane, fin, rudder and elevator	7
Wires, struts and fittings of the wing structure	15

It will be noted that by far the larger part of this resistance is made up of the body itself. A large part of the body resistance, however, is really used in providing cooling for the engine, whether it is an air-cooled or water-cooled engine. Whether the radiator is let into the body or is external to it does not appear to make a great deal of difference. The body is also of greater resistance than it need be, as it is necessary that the pilot shall have a good view and shall not be entirely inclosed. Bodies round in section are somewhat lower in resistance than the square bodies, but the difficulties of manufacture generally make their use undesirable. It is not likely that we shall be able to reduce the body resistance to a very great extent unless we can use a motor which does not require external cooling. It is true that it would be possible to use the complete surface of the body or of the wings as a radiator and by this means the waste of power would be negligible, but in order to do this the radiator becomes an impracticable and heavy piece of apparatus.

The resistance of the landing gear is considerable and it is difficult to see how this can be much reduced. It has been suggested by many people that the landing gear could be stowed away inside the body while the aeroplane is in flight, and no doubt in the future this may be done. It is, however, very difficult to design a folding landing gear without an undue sacrifice of weight.

Digitized by Google

Another factor which influences the resistance of the aeroplane to a considerable extent is the increased resistance of the parts of the aeroplane that are in the slip stream of the airscrew. The allowance to be made for this is not known very definitely, as in either a tractor or pusher aeroplane the resistance of the body itself tends to increase the efficiency of the airscrew.

Thrust Available for Flight

The thrust available from the airscrew varies directly as the horsepower of the motor, directly as the airscrew's efficiency, and inversely as the forward speed of the aeroplane. If the efficiency is constant the thrust available at any speed will depend upon the horsepower of the motor, consequently the weight per horsepower of the whole aeroplane is an expression for the ratio of thrust to weight of aeroplane. As in practice the efficiency of the airscrew does not vary very much, and as the resistance of modern-day aeroplanes per pound of weight is fairly similar, it is possible to predict rather roughly the performance of the aeroplane simply from the weight per horsepower figure.

There is considerable difference between the best attainable efficiency and that obtained under certain conditions.

As Lanchester has shown in *Aerodynamics*, for maximum airscrew efficiency the pitch must be a little greater than the diameter. From first principles also it is easy to see that the diameter must be a certain minimum so that the loss in the slip stream shall be small. Now it is always convenient to have an airscrew as small as possible, for when it is smaller it will be lighter and less in the way.

Again, unlike the screw of a ship, the airscrew has to work at bigger thrusts when the aeroplane is going slow and climbing than when it is going at full speed on the level. As a consequence the airscrew of a modern aeroplane nearly always has its maximum efficiency when its effective pitch is at its largest, i.e., when it is going fast, and its efficiency is lowest when the pitch is small, that is, when the aeroplane is climbing.

Another disadvantage when the aeroplane is climbing is that the engine is more heavily loaded and in consequence the airscrew goes slower. With engines as they are this always means less horsepower. We need, therefore, either a change speed gear or an airscrew in which the angle of the blades can be changed. This will avoid a drop in horsepower and to a lesser extent the loss of efficiency when climbing. We also need, however, a propeller of varying diameter so that combined with a change of angle and a suitable engine speed we should get nearly a maximum efficiency under all conditions.

There is not much room for improvement in airscrew efficiency working under the best conditions, as the efficiency is as high as 85 per cent. When climbing, however, the efficiency will frequently drop to less than 65 per cent.

Attempts at variable pitch or variable angle airscrews have been made, but none seem to have reached a practicable stage. The design of such a screw is quite possible and no particular invention is required to make it a success. As the demand undoubtedly exists, variable pitch airscrews will be made successfully and will become a standard part of the aeroplane equipment in the near future in all probability.

Performances of the Future

The aeroplane flown by the Wright Bros. had a speed of 30 to 35 m.p.h., and we have in a few years made aeroplanes that fly four times as fast. What then are the prospects of the future? Before considering this we must consider the effect of height on the speed at which an aeroplane flies.

The speed drops steadily as the height is increased, i.e., as the density of air is decreased. The reasons for this drop in speed are rather too lengthy to state in this paper. Very briefly, the resistance of the aeroplane and the horsepower of the engine each fall off when the density of the air decreases, but with engines as now designed the horsepower falls off faster than the resistance.

It is now proposed to consider what speed we are likely to attain in an aeroplane of the future flying at a height of 10,000 ft. As it is a hypothetical aeroplane engine, we are entitled to assume that all the improvements outlined in the preceding paragraph are incorporated into it. The assumptions we will make are: (a) That the planes have variable camber. (b) That the motor unit weighs 2 lb. per horsepower and will maintain this horsepower at all heights up to 10,000 ft. (c) That the body is the best possible shape, completely inclosed with no external fittings. (d) That the landing gear shall be folded inside the body during flight. (e) That the airscrew efficiency shall be 85 per cent. (f) That the percentage of useful load carried shall be 15 per cent. (g) That the duration of the flight shall be two hours.

Assuming that the weight of the structure is as at present, the weight per horsepower of the complete aeroplane will be 6.4 lb. As we are considering a faster aeroplane than is at present made it may be as well to allow a little more weight for the aeroplane structure and we will assume that the weight per horsepower is 7 lb.

We will now turn the percentage weights into pounds by assuming that the useful load is to be 450 lb., which may be two people and luggage or perhaps one man and mails. The gross weight of the aeroplane will therefore be 3000 lb. and the horsepower of the motor ·430. We will imagine that the aeroplane is of a type in which there is practically no resistance due to the slip stream of the airscrew; also that the motor requires no external cooling. In order to accommodate the engine and crew we will consider that the biggest cross-section of the body is 12 sq. ft. approximately round in section. The resistance of such a body will be about 2 lb. to the square foot at 100 ft. a second forward, i.e., 24 lb. in all.

The resistance of the rest of the aeroplane by careful design can be kept down to 16 lb. at 100 ft. a second; consequently at that speed the total resistance other than the wings will be 40 lb.

The area of the wings necessary will be governed by the speed at which it is considered reasonable to land; taking 60 m.p.h. as a possible speed and assuming that the planes can be converted into a deeply cambered section for landing, the permissible loading of the aeroplane will be 15 lb. per sq. ft., making a total surface of 200 sq. ft.

We will now take a speed of 350 ft. a second, or 240 m.p.h., and find the horsepower required at a height of 10,000 ft., i.e., where the density of the air is 0.74 of the normal. The wing drag may be taken as a fifteenth of the weight as with wings of varying camber we shall be able to get a high lift-drag ratio even at a small lift coefficient. The resistance due to wing drag, therefore, will be 3000/15, which is 200 lb.

As the aeroplane is flying at 350 ft. a second, the body drag will be 3.52 times what it was at 100 ft. a second, which will be 490 lb. As, however, the air is 26 per cent. less dense, its resistance will be reduced to 364 lb.

The total drag will be the sum of the body drag and the wing drag, 564 lb. in all. Taking an airscrew efficiency of 85 per cent on the power required for flying will be very nearly 430, which is just the power available.

The example just taken may seem fantastic to many people here to-night; it must be remembered, however, that when the Wright Bros. were flying at 40 m.p.h., speeds of 150 may have seemed to them equally fantastic. On the assumptions we have made it is reasonably certain that a speed of four miles per minute can be obtained, and as motors of less weight per horsepower become available there is no reason why this speed should not be exceeded.

The rate of progress in increase in speed will depend upon the demand for speed. If war were to last it is almost certain that speeds of much more than 200 m.p.h. would be common in quite a few years from now.

Stability and Control

In the original Wright aeroplanes no attempt was made to obtain stability. The aeroplane was definitely unstable and required considerable care on the part of the pilot to keep it in equilibrium.

The early French aeroplanes were a little better in this respect, but the first aeroplane to prove that it really was stable, i.e., it could fly without control, was that designed by Lieut. Dunn. This was an aeroplane of somewhat curious

Digitized by Google

construction and never became a success, although it certainly was stable; on a windy day it was somewhat difficult to persuade it to fly on a straight course and its control when landing seems to have been insufficient. Lieut. Dunn, however, certainly showed that a completely stable aeroplane was a possibility.

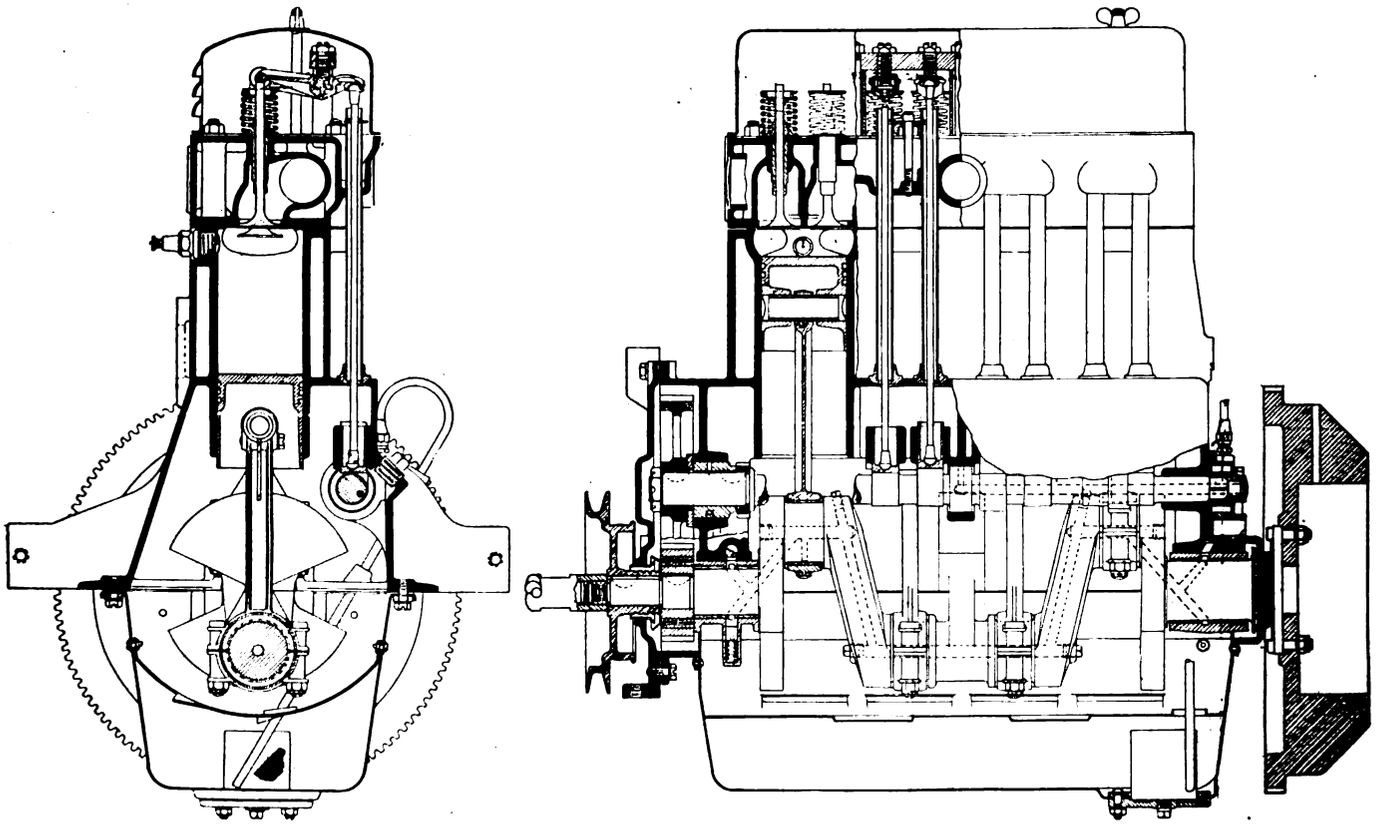
About the time at which Dunn was making his experiments certain German designers claimed that they had produced a stable aeroplane. No records seem to exist of any test that proved their aeroplanes were stable, and in any case they certainly suffered from lack of control.

The first aeroplane of normal type that was proved to be stable was produced as the result of experiments carried out by the late Edward Busk. An aeroplane known as the R.E.-1 was used for the first experiments and it was modified until it was made completely stable. Tests were carried out in order to prove that this aeroplane really was stable, and with Busk as pilot, carrying Colonel Sykes as observer, a flight was made from Farnborough to Salisbury Plain, in which the only control used was the rudder, and this for part of the time at least was worked by Colonel Sykes.

Since that day most English aeroplanes have been designed to be stable; it has been found that for purposes of fighting an aeroplane that is extremely controllable is necessary, and it has been also found that if an aeroplane is made too stable the controls are apt to become too heavy to make the aeroplane sufficiently sensitive. In modern-day aeroplanes intended for war purposes the aim of most designers is to make the machine just comfortably stable over the range of speeds used in ordinary flight, but to provide sufficiently large controls that the inherent stability of the aeroplane can be entirely overcome.

It is often asked, if we have stable aeroplanes why do we still have flying accidents? It would be quite possible to design an aeroplane in such a way that whatever the pilot did with the controls he would be unable to upset the equilibrium of the aeroplane. Such an aeroplane, however, would be valueless for fighting, and as practically all aeroplanes nowadays are made for war purposes there must continue to be an element of danger for the unskilled pilot.

Increase in speed and the increase in controllability both tend to increase the stress that will be put on the structure of an aeroplane in flight. Experiments in the increased loads that are likely to occur when doing sharply banked turns and loops have shown that the load is frequently increased to three or four times the normal.



Structural Strength and Size

Present-day aeroplanes have to be very much stronger than before. Modern machines that are expected to maneuver rapidly are not considered tolerably safe unless the wings can support at least six times the weight of the aeroplane. Fortunately, large aeroplanes for peaceful purposes will not be required to maneuver very rapidly. This fact will have an important bearing on future possibilities.

In an earlier paragraph it was stated that the proportional weight of the aeroplane parts proper was more or less constant. This applied only to machines of the sizes that are used now, *i.e.*, up to about 6 tons loaded weight. As aeroplanes are made bigger, if they are designed on similar lines, the weight of the wing structure per square foot will increase, assuming they are to be designed for the same factor of safety. It is true that on the large aeroplanes now made this increase of weight is not very apparent because greater trouble is taken to economize in the design of the wings. This increase of weight, however, is likely to be important for machines of much larger size, but as we shall be able to use somewhat lower factors of safety the weight of the wing structure will not increase as rapidly as it would otherwise have done.

We have no logical right to think that our flying machines of to-day are more than the crudest caricatures of the aeroplanes of the future. We engineers are a little apt to become so engrossed in our immediate difficulties of design that we do not see further ahead than is suggested by our own ideas, and make predictions for the future that only follow along the lines of progress that we can clearly see.

The writer has often been asked if he thinks that flying will ever become an ordinary means of travel. His answer is that he does not think, but that he knows it will become so. Ten years ago to attempt to fly from place to place was considered suicide; five years ago it was an adventure; to-day to many of us it is a very ordinary affair. A few years more and we shall laugh to think of the aeroplanes of which we are now so proud, we shall shudder at the risks we ran, and we shall travel with comfort, speed and safety.

British Cabriolet Design

Gives Limousine and Touring Car—Compared with Brougham-Limousine It Provides All Comforts of Closed Car and Gives Touring Body Besides

By George J. Mercer

Body space can be conserved by the use of the European cabriolet design in place of the brougham-limousine. The cabriolet type possesses all of the seating space and all of the light area of the brougham-limousine and in addition is fully convertible, giving a true open-car design as well.

A direct comparison of these two types is given in the illustrations, Fig. 1 being the brougham-limousine and Fig. 2 the cabriolet.

The brougham-limousine is very popular as a town car in the winter months. It has the smart features of being low and compact looking with the extra tires bedded in the fender. The fenders are the long, sloping crown shape which retain their exclusiveness because they are the most expensive to make. Additional features on this body are the moderate slanting windshield, the pillar lamps and ventilator in the cowl.

European Type Collapsible

Contrast with this the cabriolet in Fig. 2, which is commonly used in Europe, particularly in Great Britain. It seems strange that this has not been used to a greater extent in this country, particularly at a time when car owners are prone to conserve. It is fully collapsible (Fig. 3) the glass lights all dropping flush so that when open it is a good looking touring car and when closed it is a comfortable closed type. In either position it defies any criticism that it has a makeshift appearance.

A direct comparison of the two types shows that the seating accommodations, width of the doors and lights are the same. The height of the roof above the seat is slightly greater in Fig. 2 than in Fig. 1, helping compensate for the lower door entrance and insuring clear vision without interference from the roof which comes further down on the sides.

All the advantages, however, are in favor of the cabriolet in Fig. 2, as regards the dissimilar parts. All the service that can be secured from the brougham-limousine type can be secured in the cabriolet and in addition there is the advantage of having both a town and touring body. It is readily changed from one to the other and the driver in the convertible type has better protection. It is lighter in weight and altogether more serviceable.

Method of Operating

The method of operating the convertible top is shown in Fig. 3, the folding parts are shown by dotted lines in their upright position and by full lines folded down, the arrows indicating their line of travel.

The building of a body of this kind is not difficult, but it is primarily essential that the workmanship be of the best, and the parts must work free and

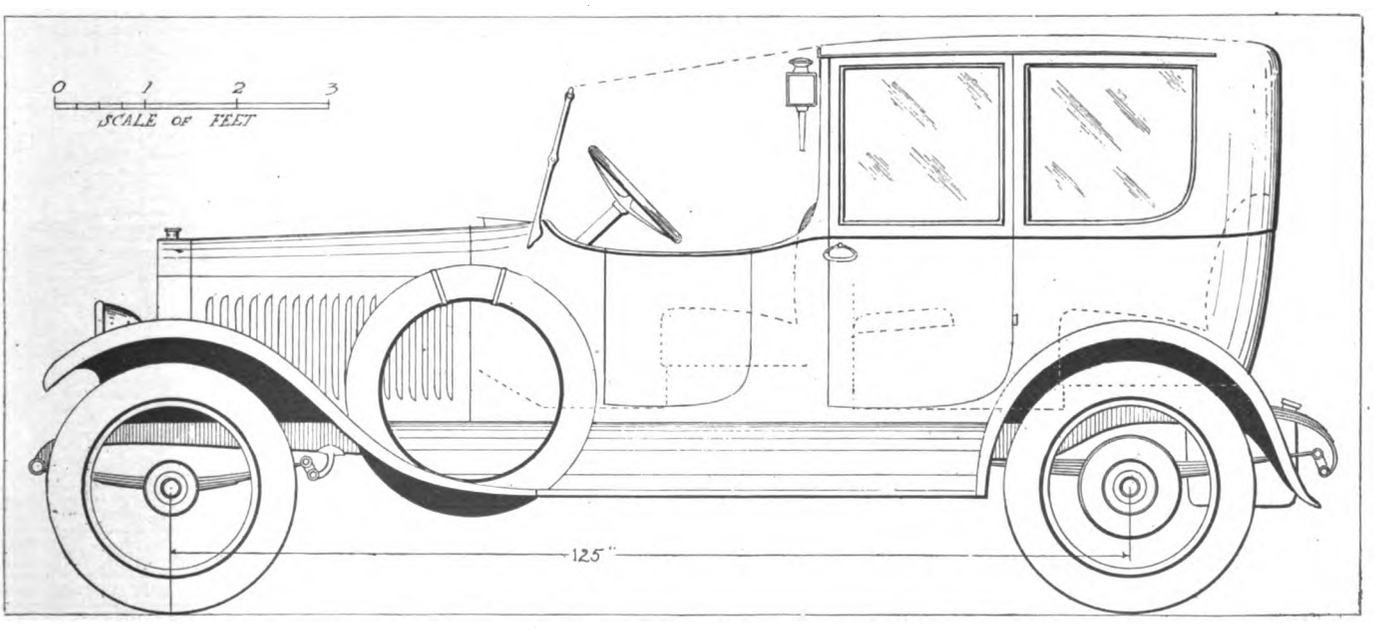

Fig. 1—Brougham-limousine which makes a popular type of closed car for winter use

Digitized by Google

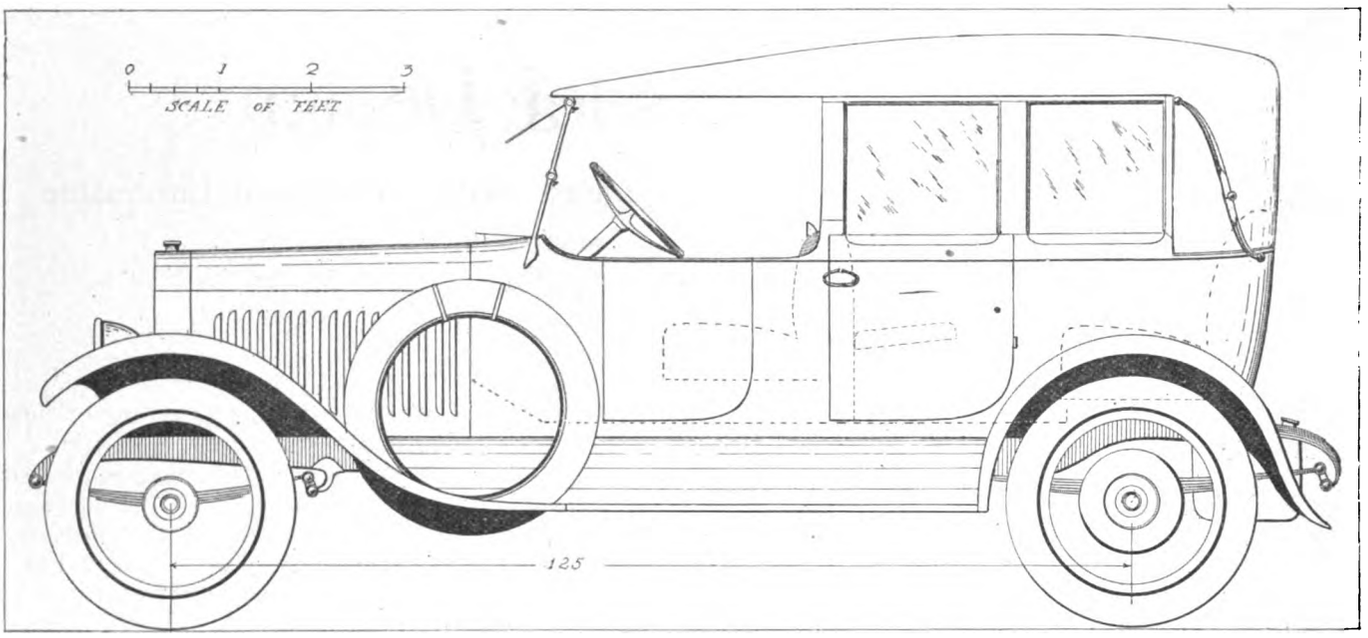

Fig. 2—Cabriolet design, popular in Great Britain, which gives all the comfort and accommodations of the brougham-limousine shown in Fig. 1, but which is convertible in addition

without strain so as to have a durable and easily operating top. If well made there will never be a complaint that this body is not so warm and comfortable as any permanent roof body. The top is entirely collapsible and the overhang or extension beyond the body at rear is short and will never cause trouble by reason of being overloaded behind. The parts themselves are not heavy individually, and as they are all tied together by hinges they serve to brace themselves and by resting one on the other the weight is well divided, thus assuring good, durable wearing qualities.

This style of top is not confined to any particular length of body. It can be either longer or shorter than the illustration. There are sufficient bows to keep the roof in proper shape.

There is almost an unlimited number of patented hinge arrangements for working this style of top; practically all will accomplish satisfactorily the result desired, but the one here used is the simplest. It is very strong as well as having the fewest number of parts and folds compactly as shown on this figure. It is of British manufacture and is in common use. To assist in carrying the weight when folding and raising there is a barrel hinge at the rear of the pillar and one outside joint on each side, the lower support of which forms the rest when the top is down. When in its lowered position the top has only a slight increase in size over the touring top, which is specially apparent when the envelope is in place.

The combination body in various forms has a great hold on the public fancy because of the general usefulness of this design. In the past a falling top body has not been in much favor on account of

A Systematic Parts List

Nature of the Parts List and the Need for It in Manufacturing Plants—Viewpoints to Be Considered in Making Up the List—A Proved System Described

By R. C. Barron
Formerly Chief Draftsman, The Curtiss Airplane Corp.

WHEN production is increased 1000 per cent in the manufacture of a machine which has not been systematically handled in the drawing room the effects are apt to be such that the engineer is compelled to give the matter attention.

The subject of a well-organized drafting room has received considerable attention, especially among the well-established automobile companies. Several writers have set forth well-defined systems.

Among the most important items in such systems is the bill of material or parts list, because through this medium the whole factory is enabled to produce the product to meet the demand of the sales organization through the ingenuity of the engineer.

Parts lists usually have been called Bills of Material. This name, which has now lost its original meaning, is fast becoming extinct.

The term Bill of Material originated in the early days when the inventor was the engineering department behind the machinery. It was customary for the inventor to make a toy or model machine to satisfy himself—or, if he needed the money, his friends—that he could make a labor-saving device. If he accomplished his desire (which was seldom the case) he built a real working model. The chances were if the machine was really good it was worked nearly to death before it was discovered that even machines wear out. Upon discovery of this important fact the machine was turned over to the machinist, who built another as near like it as he could, with perhaps a few improvements. By the time the machine had reached this stage the inventor or owner was confronted with the problem of producing several more.

They had already learned that certain parts of the machine would wear out more rapidly than others, and they had to plan on getting a record of how these pieces had been made without tieing up the machine while they used the old part for a sample to reproduce the part and have it fit. A drawing then became a twofold necessity. First, as a guide to make the part without a sample; second, as a record for future use in making replacements. However, many of the parts were of such a nature that it was possible to obtain the parts without a drawing, such as a ¼-in. bolt ½ in. long, a 1-in. square piece of wood 3 ft. long, ½ lb. tenpenny nails, etc. In order to save time and money, because the inventor usually made all of the necessary drawings, such material was either called for on the drawings or on a letter or list attached to the drawings as a part of the information necessary to construct the machine.

Bills being the most important part of the work, it was most natural to call such a list a Bill of Material.

Better Drawings Needed

As production and complicated mechanism increased, so the necessity for more and better drawings increased. Material which formerly could be called for in bulk and worked into shape on the bench had to be bought with more care, nearer to the ultimate shape, and often made in another city, or even another country.

It has been found advisable to have a drawing for every part of the machine, even if it is only descriptive, so that each part will have a number and name by which it is known throughout the organization. When this is done it becomes also advisable and necessary to compile a list of parts to make one unit.

In the well-organized factory which manufactures complicated units the pieces will first be made individually and then assembled in small units, known as bench assemblies or subassemblies, and finally in a department for that purpose, known as the Final Assembly, all the subassemblies and parts which could not be subassembled are brought together and assembled in a certain systematic way.

Digitized by Google

When the engineering department does its work well it will have a drawing for every part of each subassembly and of the final assembly.

As long as a concern is making a product of which each succeeding design or improved design is similar in construction it will be found very convenient to make a parts list which will conform with the drawings, and which is so arranged that additions may be made to take care of future models or types without disturbing the past models, which may be in the course of construction,

or which may have to be maintained for replacements or other reference.

Take the case of a concern which manufactures such products as automobiles, engines, typewriters or bicycles. Almost all of these concerns are continually redesigning and bringing out new models. Many of the parts, and often whole subassemblies of the old machines, would not be changed.

Nearly every assembled unit of any size requires, or has for commercial purposes, a few attachments to accomplish various results. These are usually known as accessories or equipments. Such equipments should be handled in the parts list as units, regardless of what model they are designed for.

The modern manufacturer also finds it necessary to furnish a small or large kit of tools, depending upon the size of the unit. There are usually several tool sets, due to changes in design, the addition of equipment, or the desires of a good customer.

Another problem which confronts every manufacturer making a unit which is subject to severe usage is that of spare parts. Very often it is arranged to make up a set of the most rapidly wearing parts and ship them with the unit. These sets of spare parts are like the tools, and vary with the design, the order, or the customer.

The parts list, then, may be divided into five distinct groups. Taken in the order of their relative importance, they are:

1. Subassemblies.
2. Final Assemblies.
3. Equipments.
4. Tool Sets.
5. Extra Parts Sets.

Each subassembly sheet will show the name of the assembly, its part number and the date of issue. All the parts necessary to construct the assembly are itemized, giving the number of the part, the name, and the number required. If another subassembly is used, it is known as a sub-subassembly, and is treated as a separate part. Its individual parts will be found on a separate sheet. For convenience, the sheet number is given in the column for remarks.

Each subassembly has a parts list sheet number assigned to it. Beginning with one (1) they are numbered consecutively. This number is always maintained, and is referred to as Subassembly Parts List, Sheet No. 1. If there should be more than one sheet required for an

Fig. 3

assembly, the first sheet is marked "Continued" and the next sheet has the suffix B. If B is the last sheet it will be marked "The End." Fig. 1 shows an example of a subassembly sheet.

All subassembly sheets are segregated in a section marked subassemblies, which is known as the subassembly bank.

If the unit is a large one, and consists of many small parts, there will be many subassemblies. Care should be taken not to make them unless the parts assembled will remain together permanently, *i. e.*, are united by riveting, brazing, soldering, welding and machining; in fact, only where the parts are mechanically worked when assem-

Digitized by Google

bled, or where the construction is such that the selection of parts is necessary to secure fits.

The reason for this is that subassemblies are made up and are stocked as single parts and are drawn on for the final assembly and for replacements. The price list and catalog for the use of the customer are made from the parts list; therefore, to protect the customer, when ordering new parts, from paying for parts on a subassembly which are in perfectly good condition on his unit, the number of pieces assembled must be kept down to a minimum.

If bench assemblies are desirable to further facilitate the final assembly they should be constructed on the final assembly floor, and their compilation is a function of that department.

Final Assemblies

These are, of course, the final product of the concern, minus the equipments, or in other words the stock units, the equipments being attached in accordance with the sales order.

In conjunction with the name of the unit, the model and type are given, otherwise they are made up similar to any other assembly, having a part number and its parts itemized.

It has been found that in making up the final assembly parts list the easiest way to insure against missing some of the pieces, and also to assist in locating parts, is to arrange the parts as nearly in the same rotation as the unit will be assembled on the assembly floor.

It is unnecessary to mention the sub-subassemblies on the final assembly parts list, but it has been found advisable to do so as a reference. Care must be taken that the numbers of such assemblies are not placed in the regular column for numbers, as it would confuse the order department when placing assembly orders. The place for the part number and sheet number in this case would be in the Remarks column. The advantage of this arrangement is to enable the record department to collect quickly all of the sheets of the parts list necessary for the construction of a unit. See Fig. 2.

These final assembly sheets are numbered with a combination symbol composed of the model and type and a letter prefix; *i. e.*, if the model were A and the type 1, the first final assembly sheet would be A1-A, the second A1-B, etc. Each succeeding sheet is marked "Continued" until the last, which is marked "The End."

The final assemblies are arranged consecutively according to priority, and separated by an index sheet bearing the model and type number as illustrated in Fig. 6.

Equipments

The question of just what parts of a unit may be considered as equipment is almost a personal one.

It is generally understood that any part or assembly of parts which can be detached and be replaced by a new set of a different design, is equipment; in fact, any parts which may be optional with the customer come under this head. For example, on the automobile, the starter, tire pump and speedometer come in this division.

The parts list for equipments is made up in the same manner as the final assembly; in fact, they are final assemblies in the case where the concern is an accessory manufacturer.

There will be a tendency, when following this system, to arrange so many parts in the equipment division that there is little left for the final assembly. This should be guarded against by the engineer taking a firm stand at the point where a change in equipment affects the performance of the product. If a change in the parts is for the improvement of the performance of the product it may warrant a change in the type of the unit.

The equipment parts list is numbered consecutively, but in order to distinguish it from the subassembly parts lists a symbol is adopted, such as EQ. The first equipment would become EQ-1, the second EQ-2, etc. If there is more than one sheet to an equipment the second sheet would be numbered EQ-1A, the third EQ-1B, etc.

Fig. 3 gives an illustration of an equipment where

there were several styles of exhaust pipes and mufflers to suit different installations of an engine.

Tool Sets

What constitutes a tool set depends upon the design, the quality and size of the product, the engineer, and (sometimes) the customer.

It may be dangerous to furnish too many tools, as the customer is liable to adjust parts which may affect the performance of the product.

In most cases, a few of the most used tools, such as wrenches, pliers and screwdrivers, cost but little, appeal strongly to the prospective customer, and are gladly furnished.

The tool-set parts list is numbered similar to equipments, having a special symbol, such as TS.

A typical tool set and the method of making up the list are shown in Fig. 4.

Extra Parts Sets

Extra parts are not always taken into consideration, but most machinery has parts of such a nature that they are easily broken or wear out much faster than the more protected or more robust parts.

A very striking example of the extra part is the needle

REPORT ALL DIFFERENCES TO THE RECORD DEPT. BY PARTLIST SHEET & ITEM NO. — DIVISION EXTRA PARTS — SHEET NO. EP6

No. 5

of the sewing machine and graphophone, or the tires of the automobile.

In any case, the manufacturer of machines always makes a certain number of spare or extra parts, depending on his production, to be retained for replacements.

The example shown in Fig. 5 might be a list of the extra parts such as would be furnished with every six engines furnished to a dealer who repaired the engines in his locality.

The extra part set parts list is, like the list of equipment and tools, given a special symbol such as EP, as shown in the example.

Changes may be made in any parts list sheet by checking the item changed in the column for that purpose and adding a new issue date; all previous checks denoting changes, unless in regard to the same item, to be removed.

This may be done with or without a notice, depending on the size of the issue and the size of the concern. It is not, particularly vital, but very convenient, when the order department is efficient and considers it necessary to insure proper attention.

It is a mistake to try to make the parts list form contain enough information to satisfy every department, as many have tried to do.

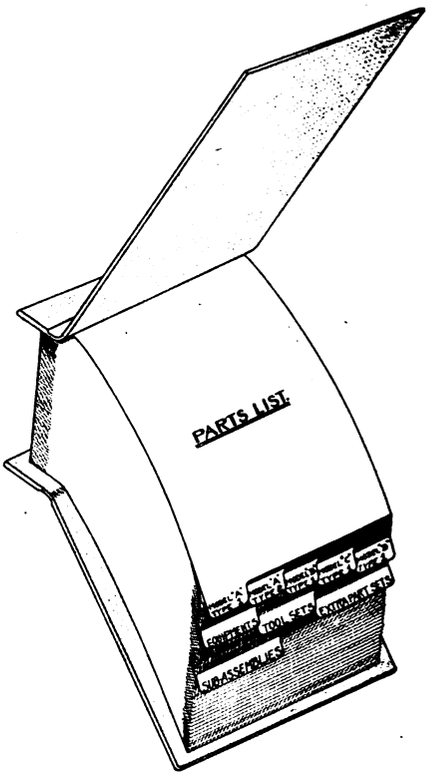

Fig. 6

Take, for example, the form shown in Fig. 7. Much time was spent in trying to produce a form which would answer many uses. The result was that it soon became a cumbersome, expensive item when filled, hard to reproduce, and harder to produce, and it was finally discarded for the more simple form.

The form shown in Fig. 1 is simple, and is doing good service where many other forms had been tried and proved failures. If other lists are desirable for temporary use it becomes a very simple matter to compile such lists.

The writer has experienced the necessity for a different parts list when called upon to furnish a complete numerically arranged list of all the parts necessary to satisfy a certain sales order calling for a model, several equipments and a set of tools, which contained over three hundred parts.

For the moment it looked as if the method of compiling

Condition of War Zone Roads in France

General Layout of the French Road System and Its Service in War Time—Traffic Conditions Behind the Firing Line—Building of Special Roads and Maintenance Methods Employed

By W. F. Bradley
Special Correspondent of Automotive Industries

THE observations upon which these statements are based were made by the writer in six months' service within the war zone as a part of the French army transportation system, namely, as a driver in the American Ambulance Corps. They cover practically all that part of the Western Front now held by the French Army; specifically from the vicinity of Nancy near the Swiss border to the Somme River, which, up to last March, marked the junction of the French and English forces.

The actual front line work was done in the Argonne Forest sector near St. Thomas and St. Menehould, where ambulances worked within 400 yards of the German first line; and on the Somme battlefield between Peronne and Chaulnes, where the work was done in the ground taken from the Germans in the great offensive of 1915. Back-line work was also done at various points within the war zone; on the famous Ber-le-Duc Verdun road; through the battlefield of the Marne, from Vitry-Le-Francois to Meaux, and in the vicinity of Amiens.

It is not possible to generalize as to conditions and phases of the road situation within the entire war zone. There is a great variety of topography. From the Somme to the Moselle, one goes from low rolling plains to high abrupt hills and rugged country. Along the line there is great variation in activity. Comparative quiet reigns in the Argonne and Vosges sectors; traffic is regular and fairly low in volume and to all purposes about as well under control as in peace times. The lines here have not moved substantially since 1915. It was in the Somme sector that I found things moving at highest tension and the transportation system most severely taxed. Here there was an immense volume of traffic moving in the entire area twenty miles back of the line; destructive artillery fire within the 5-kilometer zone; continuous heavy fighting that demanded great movements of troops, supplies and ammunition, and the necessity for the accommodation of an advancing army over ground that has hardly a spot untouched by shells. My remarks in this paper will, therefore, deal particularly with the Somme sector, especially when referring to heavy volumes of traffic.

I—PLAN OF ROADS

The original layout of the French system of highways was fortunately most comprehensive. It has filled the requirements of the present exaggerated demands in a most admirable way, and has undoubtedly been a tremendous factor in the defense against the German invasion. New roads have, of course, been constructed under special local conditions, but these instances seem to be rare and in the main, the original highways, unchanged in location, grade, or width, carry the war traffic.

Safety Roads

New roads are constructed mainly to relieve traffic from shell fire. On the eastern end of the line, among the hills, roads are often built to the leeward of the enemy. A specific instance of this is in the Argonne forest, near Four de Paris. The main concentration of reserves, supply stations, dressing stations, etc., is in a long narrow valley a few hundred yards back of and parallel to the first line trenches, which are on the other side of a low hill range. The original road was on the far side of the valley and is in sight and easy range of the enemy. It is marked Very Dangerous on army maps. An entirely new road has been built in the shelter of the hill range, hugging it closely in all the deviations of the slope. Here traffic can move in almost full security from direct hits.

Main roads are well known to the enemy and their range established by experience. In the flatter country they often run on tangents miles in length, making easy targets. In heavy actions these roads are so vigorously shelled that supply trains cannot pass except with severe losses. As a counter measure, new roads are sometimes built nearby—crooked in alignment, but in general direction paralleling the main road. Traffic is shifted between these roads to avoid shell fire or to confuse enemy airmen as to which line is actually being depended upon for service.

Control and Economy of Movement

The French plan of troop cantonments, supply stations, base hospitals, etc., is quite evidently designed with the road facilities as a basis. It is a rare thing to find heavier traffic moving than the width of road can accommodate (except, of course, on the main trunks near the first line, where congestion is unavoidable; this case will be discussed later). Each class of road from the grand highways to the little community roads seems, in a busy sector, to have just that portion of the traffic which it can satisfactorily handle. This condition is too general to be accidental, and as the result of careful planning of concentration points and the routing of movements, it is admirable and a great credit to the French engineers.

Temporary concentration camps for large bodies of troops, as we know them here, are practically unknown in the war zone. Tents, except for hospital uses, are rarely seen. Troops are quartered in villages, the houses of which are entirely commandeered for the purpose. Each house, public building and stable car-

Digitized by Google

ries a card showing the number of men it can shelter. Troops move out and new men come in, in the same day without confusion. This system is of special advantage from the transportation engineer's standpoint for it obviates the necessity for special camp roads, does away with the transportation of cumbersome camp equipment, and keeps men and materials concentrated on existing highways and village streets.

When a division moves to a new point different units of the division may be ordered to move on different routes. Marching troops are slow moving and tend to obstruct motor traffic on the main roads; side roads are better suited for them. Light motor ambulances can take a longer route, using secondary roads. Horse-drawn supply wagons can take rough side roads which have been allowed to get in bad condition. Heavy motor trucks, with low gasoline mileage and costly to repair, must have the best roads and the direct route. In such movements each unit is given its routing; it may or may not be designed to prevent congestion accordingly as the necessity exists. But the general scheme is there ready for use and it is made possible by the minute network of roads of all classes in the French system.

All cross roads and road junctions are plainly and permanently marked with distances and directions to neighboring points. This has proved an invaluable aid to effective movements of units in charge of officers, the great majority of whom are strangers in the particular locality. I cannot conceive of all the divergent movements of the present war being put through without the aid of these road signs, except with endless confusion and delay. On the other hand, they must be of similar aid to the enemy in the occupied territory. It would be an excellent plan in any retreat, or in time of invasion to have men especially detailed to destroy all road signs before the retirement.

II—TRAFFIC

At certain points and at certain times in the war zone the volume of traffic of course exceeds all limits of peace times. It combines all elements of destruction to the road surface which it uses. It is continuous and urgent. It cannot be halted for careful repairs or maintenance work to restore the road surface; yet the surface must be kept in a fair traveling condition. Travel must go on in the rainy season when the surface is softened and holes rapidly deepened by displacement of mud; and in dry summer, when the binder flies out in clouds and constant raveling occurs.

Traffic is made up of all varieties. Cavalry (very little); horse-drawn wagons and batteries with steel-tired wheels; troops with hob-nailed shoes; heavy motor trucks, and fast motor automobiles. It seemed that heavy motor trucks made up fully 50 per cent of the traffic on the main roads. It will be seen, from our American standards, that continuous traffic of the above nature constitutes as severe a test of a wearing surface as can be imagined.

Traffic on the Amiens Road

The road leading from Amiens to the front lines of the Peronne-Chaulnes sector, is a good example of extreme concentration of traffic on a main feeder of a busy front. From Proyart to the front—a distance of about nine miles—the bulk of the traffic must move at night, incidentally without lights, to avoid observation by the enemy. From Amiens to Proyart it moves principally in the day time. In both instances it is practically continuous—four solid lines of vehicles move in almost continuous procession. Slow-moving horse-drawn vehicles hug the shoulders of the roadway, leaving the center for motor travel. Fleets of motor trucks pound steadily by, in hundreds; spaced only about 50 ft. apart and traveling at an average rate of at least 12 miles an hour.

All convoys, or fleets of vehicles, move in a formation which provides an open space of 100 to 200 ft. or more after a group of several vehicles. Certain vehicles in the convoy carry a large red disk about a foot in diameter to indicate to the driver following that he is to leave space. This is to expedite the passage of fast-moving units, such as officers' cars, dispatch cars, or ambulances, which would otherwise be forced to proceed at the speed of the convoy. Even with four lines moving an open space several feet in width is usually maintained in the center. Independent units move in this, dropping into convoy spaces to permit the passage of other independents going in the opposite directions.

Cavalry and batteries are sometimes forced by traffic demands to move through the fields bordering on the roadway. It is quite common to see long stretches of main road where the effective width has been increased by what is practically an earth road on either side. Troops on the march are sometimes shunted to side, secondary or even temporary roads when the jam is great, and roadside signs indicating where this may be done are frequent. These expedients are necessary to the proper movement of wheeled traffic when a main trunk leading to a busy sector is reached. As a result this enormous traffic moves with a smoothness that is amazing.

Altogether, it is difficult to understand how any system of roads could handle traffic of such volume, continuity and destructive qualities. That it is being done in France indicates that there are lessons to be learned there by the highway engineering forces of all other nations. The various factors that make this feat possible are worthy of deep study and investigation which the nature of my army service made it impossible to give.

III—TYPE OF ROADS

The prevailing type of road in northern France is the waterbound macadam. Many gravel roads were also seen and a very few roads in the Marne Valley were found to be of a local chalky material. The latter were wholly minor roads. Except for the cobble and block streets of some of the villages, no bituminous macadam concrete, brick or any of our American so-called permanent types of construction were encountered.

The waterbound macadam type lends itself extremely well to the demands of war conditions. Material can often be found at roadside or locally, thus relieving the transportation system; maintenance and repairs can be conducted in the rough manner necessary to keeping roadways open and with unskilled labor and without special equipment. The severe test of this type would of course come in the summer, when the wear due to loss of binder in the wind and to raveling must be very great. Unfortunately, I was not in the war zone during that period and so cannot judge. I saw these roads in the early fall, however, and they seemed to be in what I could afterwards estimate as average good condition.

One is inclined to wonder just what would happen to our bituminous highway surfaces, to our 6-in. concrete, or to our brick construction if these were subjected to the continuous pounding of traffic such as occurs on the Amiens road, for instance. They would develop severe weaknesses, of course—no standard surface could withstand such wear. I believe that the difficulties in repairing them in kind would be enormous.

Digitized by Google

owing to the absolute lack of time for necessary refinements. Modern war traffic over our standard country highways would undoubtedly bring serious problems of maintenance and repair.

IV—GENERAL MAINTENANCE AND REPAIR

The system of maintenance and repairs to road surfaces in the war zone might be summed up in the phrase, "do the best you can while you can." Work of this nature, in its true sense, cannot be performed with traffic demanding all of the roadway continuously. Makeshifts and rough work must be resorted to—such repairs as are possible must be made. When, and as soon as, the shifting of the point of big actions permits, complete repair and restoration of the road must be undertaken. It seems to be the French policy to keep all the important roads in best possible shape against the time when they must be used unsparingly, unmercifully and without repairs. No effort to accomplish this is neglected. In no other way can the excellent service given be explained.

To illustrate: On the eastern end of the line there was comparative quiet last winter. The big actions in the Argonne and around Verdun were over. They had unquestionably brought enormous destruction to the roads in these sectors. The Bar-le-Duc Verdun road, about 50 miles in length, had carried, during the months of the attack on Verdun, a continuous chain of about 5000 motor trucks night and day. The total wear and depreciation of the surface must have been terrific. But I found this road and the other main roads of these sectors in excellent condition; with smooth surfaces, full cross-section, clean waterways and with plentiful rock supply stored on the sides—in short, to all purposes, as good as new. Quite evidently these roads had been repaired and thoroughly renewed without loss of time immediately after traffic congestion ceased. They are now as ready as they can be made to withstand the strain of another great traffic concentration should it come—and it may come any time. This is true preparedness—the result, no doubt, of the old French thoroughness in road construction and maintenance, combined with the lesson of experience in the importance of serviceable roads to effective army operations. Its results are remarkable, especially when one considers the demands for labor and materials for purely offensive and defensive operations.

Worst Roads Near Firing Line

The worst roads are encountered very near the front, in an active sector. The artillery fire of the enemy within say, 5 kilometers of the front line, is very destructive to the roads and in a great measure prevents effective repair work. This is particularly true in the Somme sector, where the country is flat and practically treeless, and so without protection to the roads or the traffic moving on them. Most of the time the enemy fire is directed on the roads and batteries in the zone from 2 kilometers to 4 kilometers back of the line.

Here, too, the entire area was swept with creeping barrage fire during the Allied offensive and advance. Roads were destroyed and there has been no opportunity to rebuild them in good shape. It is a fact, therefore, that even the main road is in very rough condition after one advances beyond the position of the French first line trenches before the offensive—that is, in recaptured territory. Ambulances, for instance, are obliged to run largely in low gear from this point to and from the advanced dressing stations. The roads are passable but extremely rough. In this sector, too, upkeep of roads within about 2 kilometers of the front line is not attempted. Their position is too exposed and the shelling too severe. No vehicles approach the front beyond this limit, except the small "soup kitchen" and light supply wagons, and these only at night.

V—MAINTENANCE AND REPAIR

My study of the details of maintenance and repair was of necessity confined to what I could see by chance in passing along the highways on service runs. It was never possible to stop for discussion with the officials in charge or to examine the work closely. Often, however, I passed a single piece of work so frequently that I became fairly familiar with it. I was able to pick up some information from officers in cantonments, which, coupled with actual observation, gave me such knowledge of the system as I here present. It is obvious, however, that this discussion cannot go deeply into this very interesting subject. But with these reservations the statements are, I think, true to fact.

Nature of Work

The work very naturally divides itself into the more or less continuous addition of new material without interruption or real displacement of traffic—which can be called maintenance; and the renewal of the wearing surface completely, or repair.

Maintenance

The pre-war continuous patrol of road surfaces by individual cantonniers is not in evidence in the war zone. It is, of course, unnecessary to keep surfaces in the degree of excellence obtained in peace times. The little roadside houses of the cantonnier are now abandoned or used for storing tools. Maintenance, in the war sense, is practiced principally on the more important roads carrying heavy traffic. Two methods are in use:

1—Loose stone is placed by hand shovels in the surface depressions and compacted by traffic. The work is done at periods when the traffic is lightest. Usually the stone has to be placed hastily and in a rough manner. Sometimes it must be cast entirely from the sides. Compaction takes place very quickly under passing fleets of heavy motor trucks with solid double 4-in. rear tires. In the continuous wet weather that was the rule last winter the results were surprisingly good.

2—The surface is first roughly cleaned of excess mud. Working in short periods whenever traffic permits, layers of material about one stone thick are placed in narrow, longitudinal strips and rolled into the surface with steam rollers. The resulting surface in this, as in the first method, is irregular and rather rough, but the main object, which is to restore sufficient material to maintain full thickness, is accomplished.

Repair

Repairs to main trucks in busy sectors are not attempted except for the filling of shell holes. Material must be supplied by the methods above described and repairs postponed until such time as traffic will permit.

Surfaces are renewed by the half-section plan of operation. The old surface is scarified by hand and stone added to the desired thickness. Earth and clay seem to be freely used to expedite quick binding. The new surface is compacted with steam rollers.

Rock supply is often brought in by rail. Usually, though, there seemed to be a local source within wagon haul. The rock is broken by hand, either at the quarry or at roadside. Supply piles are kept stacked at roadside for maintenance and repair.

Digitized by Google

Building stone from villages demolished by shell fire is another interesting source of road material. Stone is so generally used in the construction of French villages that in many cases a large amount of material convenient to the location of the work can be obtained in this manner. In the Somme sector one of our advanced posts was a dugout at the crossroads, which had once been the center of the village of Etrees. Originally it was 2 kilometers long and had a population of about 1500. I was amazed at the completeness with which it had been destroyed—there was hardly a sign of the building that must have stood there, not a wall or a portion of a wall standing. I soon learned that the underlying reason was that building stone had been carried away for road purposes.

Brick is also obtained from ruined buildings for road purposes. I saw an original and interesting type of surface reconstruction in the vicinity of the big base hospital at Marcelcave. A 3-in. course of brick bats, salvaged in this way, mixed with a small percentage of crushed stone, compacted with a steam roller, was used. The finished surface was quite smooth and looked like a red clay road of our South. Wet weather continued during the time this surface was under my observation. Under this favorable condition it was an excellent road. It was probably recognized as a temporary expedient and will be in some manner strengthened to withstand dry summer weather.

Labor Used

Fighting men are not used for road work. All road work is done by men over the military age, by prisoners of war and by Anamites. Prisoners of war may not be and are not, worked within the fire zone—that is, in ordinary range of their own guns. Manual labor on the roads is also optional with them and they are paid therefor. Great numbers of them may be seen at maintenance and repair work, however.

The Anamites are soldiers of Chinese appearance from the French province of Anam in Asia. They do not, I understand, believe in warfare and are used for guard duty well back of the lines and are apparently the main source of road labor. In winter they are largely employed in clearing roadways of snow and scraping from the surfaces mud, which collects in enormous quantities.

VI—GENERAL CONDITIONS

As stated in the beginning of this paper, my work by good fortune carried me over many hundred miles of roads of all classes in the war zone. The average condition of these roads was far better than, under the circumstances, I expected. The first and second-class highways are kept in relatively excellent condition. The community roads have, in very many cases, gotten into rather bad shape. They are often extremely rough with big holes, but they are hard surfaced and carry their traffic with safety from miring, if without comfort. This neglect of minor roads at certain points is evidently deliberate. It is true economy that decides it. These roads are used almost entirely by horse-drawn vehicles, which are not seriously handicapped or damaged by them; in their ordinary use speed is not essential; the distance traveled over them in reaching a second or first-class road from the particular village is always short. The labor and materials necessary to their upkeep can be expended with greater effectiveness on the main roads. It comes back to our own policy and basis in the design of American road system; 80 per cent of the traffic on 20 per cent of the road, and I think that the ratio in favor of the concentration of effort on main trunks is even more marked under the peculiar requirements of war traffic.

VII—CONCLUSION

It is evident that the French road system has made good. I cannot conceive of any road system in the world designed without knowledge of the present demands meeting the situation as well; indeed, it almost seems that the French system *must* have been planned for just the present conditions. Its basic theory was certainly sound. The following features of its design have proven of special advantage at this time of crisis when so much depended on its carrying the war traffic efficiently, without delay or confusion, and with economy of effort:

1—**Grade**—The prevailing grades are very easy, permitting heavy loads for horse-drawn vehicles and faster speeds for motor convoys. Location lines are found to follow contours in almost all cases. This has made for easier maintenance and easier rebuilding after destruction.

2—**Drainage.**—The drainage systems, surface, side and subdrainage seemed to be practically perfect. Outside of villages I do not recall a single instance of poor drainage on a first or second-class road. This has been a considerable factor in giving durability under the war traffic.

3—**Foundation.**—Without adequate foundations, the main roads would have long ago completely failed. Maintenance, care or addition of surface rock could not have saved them. But these roads, even the worst community roads, stay solid and traffic does not mire or stick in soft stretches of broken sub-base soils. This is one of the great lessons driven home; good foundation and adequate thickness of pavement.

4—**Width.**—Width of traveling surface has been most important to army transport. Some of the grand highways, main feeds to the front, have a width of about 33 ft. between shoulders. Even this is crowded to capacity most of the time. How great a factor these widths have been to the success of the French army cannot be estimated nor can we guess the difference in offensive and defensive results, if they had been, say, the 18-ft. American standard.

5—**High Ratio of Road Mileage.**—The landscape of France is a veritable network of roads. The number of miles of road per square mile of territory must be at least double—probably more—than in the United States. Inasmuch as these are all improved roads this has been of great service to army movements. Between two given points several routes may be selected, none of which will greatly exceed the most direct route in distance. To aid in the understanding of the continual large movements in the war zone, I should have, perhaps, explained earlier that divisions are constantly shifting location from one sector of the front to another; from the rear of the war zone to the actual front; in the very active sectors, a particular division may be in the trenches only a few days—two weeks is said to be the average. It is this feature—sometimes overlooked—combined with demands for munitions and supplies, which accounts for the great burden of traffic these roads must bear. The dispersion of travel over different routes made possible by the high mileage ratio is, therefore, another great advantage of the French plan.

6—**Road Signs.**—The military advantages of this feature have been discussed—they have depended on the fact that the work was done comprehensively, accurately and for permanence. The uniformity of signs throughout the country enhances their value.

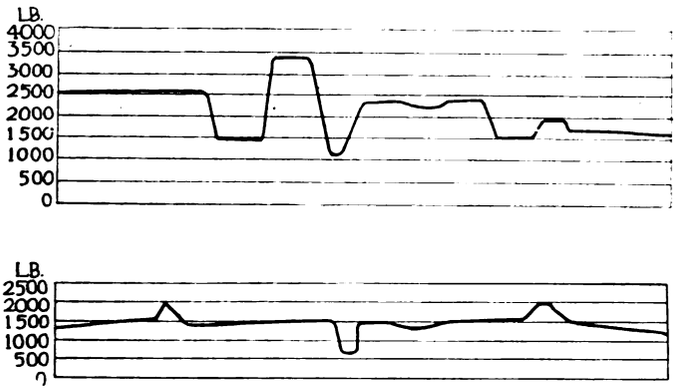
An Agricultural Power Unit



Some Factors Governing the Design of a Small Tractor—Problems New to the Mechanical Engineer Involved—A Variety of Possible Types Considered

Part II

By Alan E. L. Charlton

From the tests at 2 m.p.h. (see Fig. 7) when the drawbar-pull is 500 lb. per share, the curves in Fig. 8 have been got out in which the important effect of gradient is indicated. For four shares and a gradient of 1 in 10 it will be noted that the load at the engine is 23 b.hp., and it is desirable that this should be obtainable if not inconsistent with the other governing factors of the design, for with four shares instead of three, 25 per cent extra ploughing will be effected for the same cost of labor.

Weight of tractor, 3¼ tons.
Weight on driving wheels, 5000 lb.
B.hp. of engine = 18·75.
Driving wheels, 4 ft. 6 in. dia., 15 in. wide.
Plough, Ransome, 3-share, cutting 6 in. deep, 9 in. wide.

Upper Graph—Test No. 1

Ploughing at 1·57 m.p.h. in stubble. Stiff clay land.
Mean drawbar pull, 2300 lb.
Mean drawbar hp. = 9·65 = 3·21 hp. per share.

Lower Graph—Test No. 2

Ploughing at 2 m.p.h. in stubble. Medium soil.
Mean drawbar pull, 1500 lb.
Mean drawbar hp. = 8 = 2·66 hp. per share.
Rolling resistance of tractor with spuds on = 277 lb. per ton.
Power used in ploughing = 8·0 hp. = 42.5 per cent of total hp.
Power used in rolling res. = 4·8 hp. = 25·5 per cent of total hp.
Power used in transmission = 5·95 hp. = 32 per cent of total hp.

Fig. 7—Tests of Two-Cylinder Paraffin Tractor

From the tests made in dragging the tractor, the 900 lb. drawbar-pull for a 3¼-ton tractor is equivalent to a rolling resistance of 277 lb. per ton on land. As the tests show the loss in the gearing of the tractor is 32 per cent of the total power; had the gear of this tractor been constructed on the lines of motor car practice a considerably higher efficiency would have been obtained.

From the other test at 1.57 m.p.h. the drawbar-pull is 2300 lb., or 766 lb. per share, the drop in speed allowing the engine to deal with the stronger land. The peakiness of this curve shows the value of large flywheel effort on the engine.

The highest power which a tractor when acting as a stationary power unit is called upon to provide, is generally accepted as that for threshing.

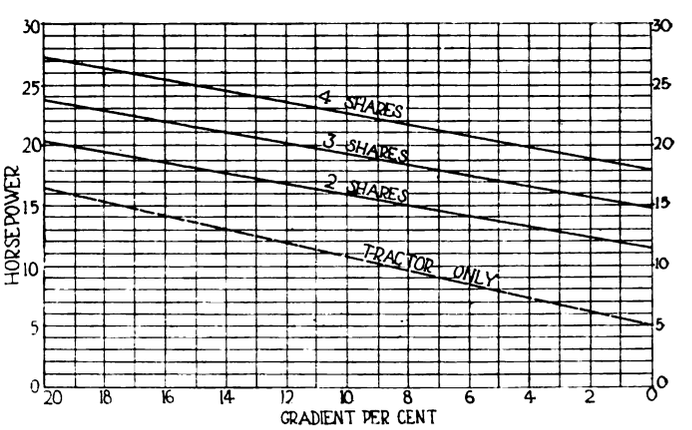


Table Fig. 9 gives an approximate power curve for different sizes of threshing machines. From this it will be seen that 20 hp. is not exceeded, though it is usual to allow 25 hp. for large machines. For grinding the powers are less.

Summing up now, and allowing a margin of safety on the results so far arrived at, the fundamental values for the multi-purpose tractor may be taken as—

	Power Reqd.	Driving Axle Loading.
Road Work	18 to 20 hp.	4400 lb.
Land Work	23 to 25 hp.	"
Farmstead	20 to 25 hp.	Stationary

Though the following observations are not fundamental they form very important considerations in the design of a tractor.

The Engine.—Any consideration of the engine must begin with the conditions under which it has to run on a farm, the inexpert attention likely to be given to it being an important factor. Generally, while this necessitates robust construction, it also calls for a low power rating or a considerable reserve of power, and probably the factors of low speed, large cylinder capacity for power required, strength and simplicity of parts are the main ones. That the engine must

Weight in working order with 3-share plough, 3 tons.
Ploughing speed, 2 m.p.h.
Rolling resistance of Tractor with spuds on, 280 lb. per ton.
Furrows, 6 in. deep, 9 in. wide. Gearing efficiency, 80 per cent.
Pull required per share, on stubble land, 500 lb.

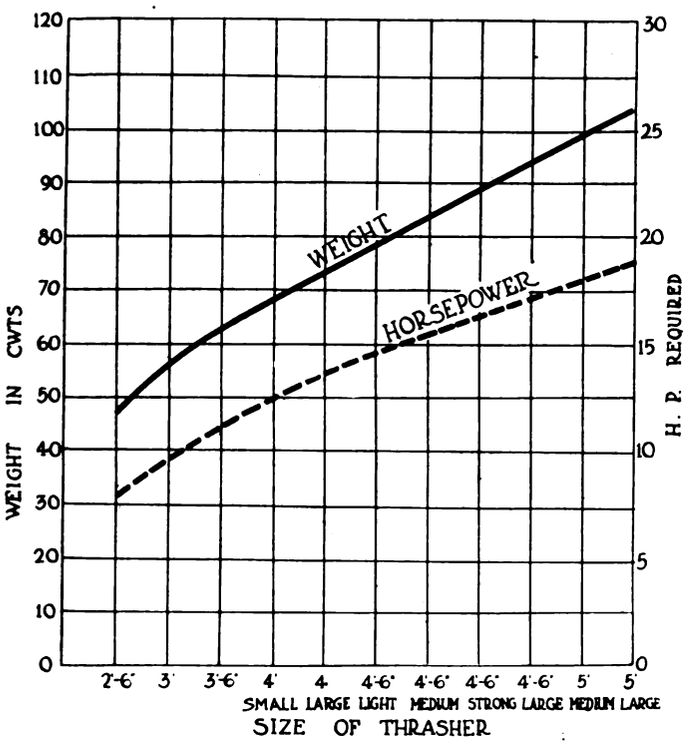

Fig. 8—Power Required on Gradients Ploughing Medium Soil.

operate on kerosene is a *sine qua non*, and further, it is preferable that it should develop its power without water injection.

The gain to be obtained by the use of crude oil in a high compression engine would justify the greater refinement of the engine, though there is greater difficulty in obtaining the fuel, kerosene being probably the most universally and readily obtainable of all oil fuels. On the other hand, such an engine

Digitized by Google

running on kerosene would probably use up to 30 per cent less, a very material and important saving and one which should induce the engineer to persevere with this type; the fact that the automatic-ignition of this type removes the risks of all electrical gear must be borne in mind. It should be quite possible, however, to secure better economies with the ordinary engine than are at present customary. It may be taken that the consumption per acre in practice is 3 gal., often more, sometimes less. A 20 hp. tractor has probably an average load of not more than five-eighths of the maximum, or say 12½ b.hp. (see dynamometer readings—3 shares, plus allowance for stoppages and headlands). Taking 2 hr. per acre, this gives, say, 12 pints per hour or 0.96 pint per brake horsepower. This result is not at all a bad one, and is probably much better than what is actually taking place in day to day work when the tractor is run by an ordinary farm hand. It should be possible to cut it down to 0.85 pint per brake horsepower, or with a high compression engine to 0.6 pint or even less.

The type of engine used, whether vertical or horizontal, would in practice largely depend upon the plant of the manufacturer, four-cylinder vertical engines being naturally adopted by the motor car engineer, whose factory is suited to that type; where factory considerations do not step in it might very reasonably be claimed that the horizontal type is to be preferred. It has frequently been found in practice with vertical engines not possessing vaporizing devices in the engine cylinder, that some of the kerosene fuel passes the pistons and mixes with the lubricating oil in the crank chamber, with a consequent thinning of the lubricant, which causes excessive wear on the main and crankpin bearings. It is not suggested that there are not many effective kerosene carbureters on the market, but rather that, despite these, with the class of labor available on the farm for operating the tractor, such action will frequently take place in starting up and on light load.

The horizontal engine gets over this difficulty inasmuch as excess kerosene will drain off through the exhaust valve before reaching the piston. A form of inlet valve which has been very successful is shown in Fig. 10. It will be noted that the hollow head, which is kept hot by the cylinder temperature, is arranged so that the entering gases in passing at a high speed through the venturi will impinge upon the hot walls; this forms an effective and compact vaporizer, and at the same time being in an inverted form, is self-draining. It must not be forgotten that the hot bulb engine can work with tube ignition, thus cutting out the electric installation, which is of all parts of the tractor probably the least understood by the farm hand; incidently, the running cost is reduced, as gasoline is not required for starting up. Thus such an engine could be arranged to operate by tube with but trivial alteration, in case of failure of the electric ignition.

The water injection, so often found in the high-speed engine of the vertical type, cannot be said to be conducive to long life; it was tried years ago in gas engine practice and eventually dropped.

The vertical quick running type can be and is manufactured at a less total weight, and this has been an additional reason for its use on light-weight tractors. It is, however, quite reasonable to ask whether, despite our being used to comparatively high speed engines on motor cars and wagons where the average load is low, and the quality of fuel and the attention good, a speed of 500 r.p.m. can be exceeded under the conditions of farm service, quality of labor, heavy ploughing loads and kerosene fuel, without a more than proportionate risk in wear and tear. Fig. 5 shows diagrammatically the two types of tractor, of which there are, of course, many variations.

Further, it is considered desirable that full power should be obtained with a mean pressure of only about 50 lb. per square inch, and that as in the horizontal type of engine the vaporizer should be in the cylinder head and allow of easy drainage for the use of low grade fuels. A suitable arrangement has already been described in Fig. 10.

It is quite true that the high speed engine reduces the weight of the tractor, but in view of the necessity of giving a reasonably long life under the conditions of farm usage, it is debatable if this is a wise policy. A comparison with a light-weight tractor on a basis of cylinder capacity indicates that these tractors obtain their light weight per horsepower largely by high engine speed and rating.

Flywheel Effect.—It is very desirable to arrange for ample storage of power in the flywheel of the engine to provide for the momentary excess required when meeting hard places, whereby the engine is subject to less strain, and the fuel consumption should also benefit. In the horizontal type suggested the flywheel effect is sufficient to provide 50 per cent

Type of Tractor	Weight, Lb.	B.H.P.	Bore, In.	Stroke, In.	Revs. per Minute	♀p Lb. per Sq. In.	♀p Wt. Tons	Vol. Swept per Min. Cu. Ft.	Vol. Swept per B.H.P. Cu. Ft.	Vol. Swept Wt. Tons
Four-cyl. vertical light type tractor.	3000	25	4¼	5¾	900	67	50	340	13.6	254
Two-cyl. horizontal multi-purpose tractor.....	5600	28	7½	11	475	48	10	534	19	214

power increase for about 30 sec. In the light tractor with a quick running engine there is usually considerably less power storage in the flywheel and the engine must bear directly the extra demands and shocks.

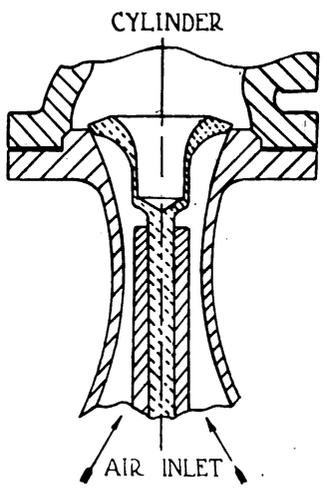

Fig. 10—Paraffin vaporizer

Cooling.—Two methods are in vogue for cooling the engine—in the one the motor car system, a radiator, fan and circulating pump are used, and in general the whole conforms very much to the standard practice in this respect. In the other system tank storage is adopted, the cooling of the motor being obtained through the loss of heat, due to evaporation from the open tank (the released latent heat of course effecting this).

The tank system is simple and is more fool-proof in its working. It allows of almost any sort of water being used, such as is found in

Digitized by Google

streams and drains about the fields, but on the other hand, it needs considerably more make-up water than does the radiator system. The advantage of the radiator system is the much smaller quantity of water needed, so that if water is scarce the saving in cartage may be considerable. Its disadvantage is that the radiator itself may silt up or in some way develop leaks.

Both systems are used and probably local conditions will govern the choice.

Frame.—The older type medium weight machines employed as a rule a special frame built up of rolled sections, while later designs, in order to save weight, have incorporated the frame in the general design of the machine with advantage. This feature should undoubtedly be adopted in the design of a multi-purpose machine.

Gearing.—The typical forms of gearing for the two types of tractors are shown in Fig. 5. In one we have the design based on the motor car arrangement, using either bevel or worm gears, and with a high reduction on account of the high speed engines, and in the other the design is based on that of the steam traction engine, in which neither the bevel nor worm is necessary; due to the cross-setting of the engine this type has not usually been totally inclosed. This feature, *i.e.*, the total inclosing of the gearing and the running of the gears in oil baths, which originated in motor car practice, should undoubtedly be incorporated in the other. As the test detailed in Fig. 7 indicated, the loss in the gearing is high, due probably to the exposed gears, want of alignment under load and insufficient lubrication. When the horizontal engine type is built with all gearing totally inclosed, the efficiency should be equal to motor car practice. As the reduction is less, and as no bevel or worm is employed, it is not unreasonable to expect from the horizontal engine a higher overall efficiency than from the high-speed engine design. The advantages of ball or roller bearings in the reduction of frictional losses are questionable. Published tests indicate but small bearing losses, so that any gain would be trivial.

Steering.—There are two types of steering, the single and double pivot. The one is practically the standard in present agricultural machines, as steam tractors, etc., and the other is the standard in motor car practice.

The first is simple, cheap and strong in principle, and outside agricultural work, it is chiefly used in steam wagon practice. Yet despite this, there is a general tendency to adopt the double pivot system for small tractor work, and this system, when centrally mounted so as to give three-point suspension, is to be preferred for the class of tractor under consideration, Fig. 11.

Wheel Arrangements.—Fig. 12 shows some of the arrangements of the wheels of tractors on the market, for each of which the makers claim special advantages.

It is not proposed to enter into an examination of the claims of any particular arrangement as they refer solely to land work and not to the road, their use on which is somewhat in the nature of a by-product. The need for a tractor to be an efficient machine for road work, materially narrows the field of selection, and as long practice has proved that, for the power contemplated, the two-track four-wheel machine is the most suitable, this seems undoubtedly the one to be selected as such a wheel arrangement is equally effective on the land.

The size of wheels may be 3 ft. by 5 in. for front wheels, and 4 ft. by 12 in. for back driving wheels.

It is noticeable that there seems to be a tendency in tractors now coming into use to adopt rather smaller diameter wheels (4 ft.), probably with a view to reduce weight.

The caterpillar arrangement, while entirely suitable for special conditions on the land, cannot be considered as an advisable type for regular road work.

In order to stand up to the road work the wheels of the tractor must be specially strong, though this naturally tends to increase of weight. It is true that, to save in the total weight of the tractor, light wheels might be adopted for work on the land, so designed as to be readily replaced by specially strong and heavy ones when the tractor is required to run on the road. In actual practice, however, it is prob-

Systematically Handling Income Tax Returns For Employees

Twenty-Four Men Required To Help Ford Force of 12,000 Fill Out Forms Properly

INCOME TAX

Come to the Factory Legal Department, Y-4-4, fourth floor Y building, to-morrow, after work, to make out your income-tax statement.

This statement will cover your total income for 1917.

Bring your tax receipts, land contracts, bank books, and all other papers regarding money you have received or owe during last year.

Ford Motor Company.

Fig. 1—*Summons blank which is attached to timecard bidding employee to come to office for assistance in filling out blank*

INDUSTRIAL concerns employing large numbers of men should assist their employees, and incidentally the government, by aiding in the filling out of the individual income-tax return blank.

Handling this matter on a systematic basis will not only make the matter less of a burden to employees but will also reduce the loss of unnecessary time which would otherwise be spent in endeavoring to make a correct return. This is not only true of concerns which employ a large number of foreign or unskilled workmen, but also those who have any great number of employees who are receiving more than $800 per annum.

It is not difficult to handle the matter rapidly, and the following method, which is employed by the Ford Motor Co., Detroit, can be used for any manufacturing concern, and will enable the employees to make correct returns in a minimum time and with the least amount of trouble to the government, the employer, and the individual.

For 12,000 taxable employees it requires twenty-four men to handle the job expeditiously. To put this another way, twenty-four men can take care of 500 a day. For a total working force of 2000 men it would not be necessary to have more than four, so that the proportion of men necessary to handle the work runs about two men per 1000 taxable employees.

To handle the work it requires a record book, a summons blank, a posted notice, and a supply of income-tax blanks.

In the record book is kept a list of the employees by number. The headings on the columns at the tops of each of the pages in the record book are:
Number. Name. Address. Amount paid 1917 Married.

Reference to the employee is by number, corresponding to the number on his time-clock card. The amount paid in 1917 is arrived at by taking 294 days as full time and multiplying this by the daily rate. Under the column Married is written the word Yes or No. The days absent are deducted from the 294 in the record under the column Amount Paid 1917.

How Records Are Kept

The head of the department—which may be called for the moment the Income Tax Advisory Department—keeps the record in his possession. The head of the department also plans the day before how many men he desires to take care of on the following day. He issues summons blanks in accordance with this number. These summons blanks are shown in Fig. 1. They are attached to the time-clock card of the men it is desired to call in, and, as will be noted by the wording on the card, they give the men a day's notice in advance. If there is too much congestion at the office owing to too large a number of the summons cards having been issued, it is only necessary to take the number of men desired and to ask the rest to report on the following day. The summons cards for that day are reduced accordingly.

The blank filled out is entitled "Form 1040 A—United States Internal Revenue." This is for net incomes of not more than $3,000. There are nineteen questions on this blank and an affidavit at the bottom. This is all that need be filled out unless there are other sources of income, in which case a few additional questions must be answered. The government will assign you an expert to aid you in giving advice to your employees, and he

Digitized by Google

will coach the men that you assign to this work as deputy. In this way it is quite simple for you to get an efficient force to handle the matter, and you will be able to expeditiously take care of the blank.

When the blank is filled out the man passes on to a notary, where he swears to his statements, and he then passes on to the cashier, where he pays his tax in to the latter, who issues him a receipt and takes his blank to forward to the government. It is highly important that the blank be taken at the same time that the money is taken, so that it can be forwarded to the government together with the check covering the income tax for any part or all of the employees. The blanks which go to make up the amount on the check are forwarded with the check.

Should the employee not have the money to pay his tax he leaves his blank in the income-tax advisory department, which forwards it to the government, and the latter sends an income-tax invoice to the individual who pays it directly.

There are several points to observe in working this system, one being to make any corrections in the record book at the time the employee is examined, should any errors be found.

The blank, which comes in two pages, containing the tax returns on one sheet and the instructions on the other, is torn in half at the time the employee fills out his blank; the half with the tax data upon it goes to the government, and the half with the instructions are retained by the employee for reference, either for himself or friends.

A very important part of the system is that no one should be assisted in filling out his blank unless he brings with him his summons blank. In this way the committee in charge can entirely control the number of men taken care of each day. They can also handle the men by their numerical order in the record book, and in this way avoid any necessity of having to jump from one part of the record book to another in tracing the men who come up to the committee for assistance.

Before putting the system in operation arrangements should be made with your local government authorities: first, for a man to instruct your deputies, who are in turn to assist the employees in filling out their blanks; and second, for accepting checks from your concern for the employees you are taking care of. Some concerns, such as the Burroughs Adding Machine, have found it better to open a separate account to handle this matter, the account being opened at $1,000 advanced from the treasury of the company, and then, after the money has been taken in from the employees and paid to the government, the account is closed out and the $1,000 returned to the treasury.

To sum up the steps in the operation of the system above, the course of the employee in filling out his blank may be traced:

1. Employee sees notice posted in his department to be ready, as his Federal Income Tax will soon be due.

2. Employee receives summons card attached to his clock card, bidding him come to office for assistance in filling out blank to-morrow.

3. Employee enters Income Tax Advisory Department in his proper turn, is seated at table with member of advisory committee, who assists him fill out blank, referring to record book should employee have doubt regarding his yearly income.

4. Record book used to check up statements regarding annual income or married state of employee, should such appear necessary.

5. Employee goes to notary in income-tax advisory department and swears to or affirms his answers.

6. Employee takes blank sheet which has his income-tax data upon it to cashier and deposits it with him, together with check, money order or cash covering the same. He retains other half of income-tax blank containing instructions for reference for himself or friends; or,

7. If he has not the money to pay his income tax he leaves blank with income-tax advisory department, which forwards it to government, which in turn sends invoice to individual.

8. Cashier sends income-tax blanks, together with check covering same, to government.

Laminum Shims for Engine Bearings

IT is now the general custom, in order to facilitate the taking up of engine bearings, to provide shims between the bearing proper and its cap. These shims may be either solid or they may be made up of a considerable number of very thin leaves of which one or more can be removed when the bearing has to be adjusted. The advantage of the solid shim is that it always gives the same degree of adjustment when the cap is drawn up tight. Its disadvantage is that the work of filing down the shim to reduce the bearing diameter is very tedious, and, besides, very few workmen are sufficiently expert with the file to be able to file down the shim absolutely parallel. The so-called loose leaf shim has the advantage that it permits of easy adjustment of the bearing, because all that is necessary after the cap has been removed is to take out one or two of the leaves and replace the cap. Unfortunately, there are also difficulties with the loose-leaf shims. The leaves are only about 3/1000 in. in thickness, and it is obvious that they cannot stand any hard usage. When removing a bearing cap it is a frequent experience that all of the leaves will drop from the bearing bolts and one or more are lost. Furthermore, the leaves are likely to be covered by oil and the thickness of the oil film will be different according to the temperature and the grade of oil.

A special form of shim which is claimed to combine the advantages of the solid brass shim with those of the loose-leaf shim is being manufactured by the Laminated Shim Co., New York. This shim, known as Laminum, is made of a number of sheets of brass, 0.002 in. or 0.003 in. thick, the sheets being firmly held together by a metallic binder. As far as can be seen by the naked eye the shim appears as made of solid brass. However, the nature of the binder is such that any sheet can easily be peeled off and thus the thickness of the whole shim be reduced by 2/1000 or 3/1000 of an inch. There is no possibility of loosing sheets by dropping them or of getting them covered with dirt, and the shims always remain absolutely parallel. The individual layers can be readily peeled off by means of a penknife. The advantages of such shims to the repair man are obvious.

Electrically Heated Foot Warmer

To minimize the discomfort of long standing outdoors in severe weather, an electrically heated foot-warmer has just been placed upon the market by the Westinghouse Electric & Manufacturing Co. of East Pittsburgh, Pa. While designed primarily for lookouts stationed in the bow and crow's nest of vessels, the device is applicable to the use of watchmen, sentries, doormen, traffic policemen and others whose work requires them to be out of doors continuously with little chance for exercise. It has been found that if the rest of the body is adequately clothed, a foot-warmer will insure comfort at any temperature.

Trucks Move French to Italy

By W. F. Bradley

PARIS, Jan. 1—The transfer, in the minimum of time, of big French and British forces from the French to the Italian front, when this latter was threatened by the great Germano-Austrian thrust, was one of the triumphs of the automobile. Under war conditions, which obviously exclude Switzerland, there are two railroad routes between France and Italy. The more northern one passes the frontier near Modane, by the Mont Cenis pass, 6500 ft. above sea level, and the other follows the shores of the Mediterranean. To get the armies into Italy in time to save the situation, these two lines had to be turned over exclusively to one-way military traffic, most of the trains returning empty in order not to lose time in loading. This railroad traffic included all kinds of war material, not neglecting automobiles.

Over Alpine Passes

But the railroad was not alone in taking relief to the Italian forces. There are two main passes over the Alps, one at Mont Cenis, following practically the same route as the railroad, and another cutting across very near the coast line; between these two there are a few minor passes, all of them less than 6000 ft., but often presenting difficulties by reason of the roads. All these available roads were made use of by automobile convoys, which at times passed in a continuous stream. As there has not been since the war any great amount of road traffic between Italy and France, these various routes naturally formed one-way roads, which was a fortunate condition, for even on perfectly engineered European roads the passage of incessant convoys in a mountainous district is not an easy operation. The difficult nature of the operation will be understood when it is mentioned that on some of these Alpine routes there is a continuous climb for 12 miles and an unbroken descent for 14½ miles. Many of these mountain roads are merely a ledge cut out of the face of the cliff; many of the village streets were only just wide enough for two touring cars abreast and did not give sufficient room for two trucks to pass. There were sharp hairpins which if not taken with the correct lock on the first attempt would necessitate backing and the possible holding up of the entire convoy.

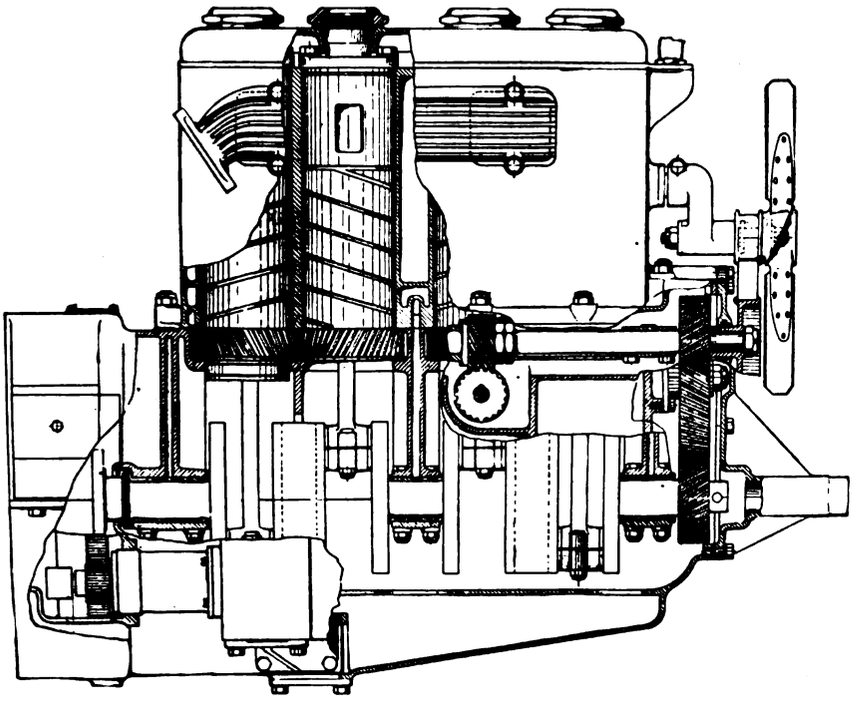
More than 100 years ago Napoleon passed over these same Alpine roads with horse and mule convoys, and the task is still pointed out as a marvel of organization. The traffic of the French and British armies which went into Italy by road in October and November, 1917, is greater than that required by Napoleon, and was much more difficult to organize, for the time element was most important; yet the whole was handled in a marvellous manner and has been passed over by the general public as almost commonplace.

Danger Signs Posted

To reduce the possibility of accidents, road signs were erected on a liberal scale. In this district direction was the least important indication. As the men did not know the roads, warning notices gave indications of all the obstacles ahead and told where the men had to change into low gear in order to get the advantage of the motor as a brake on the dangerous descents. On the long climbs it was necessary also to warn the men so that they would space out and have their sprags down in case the truck should begin to run backward.

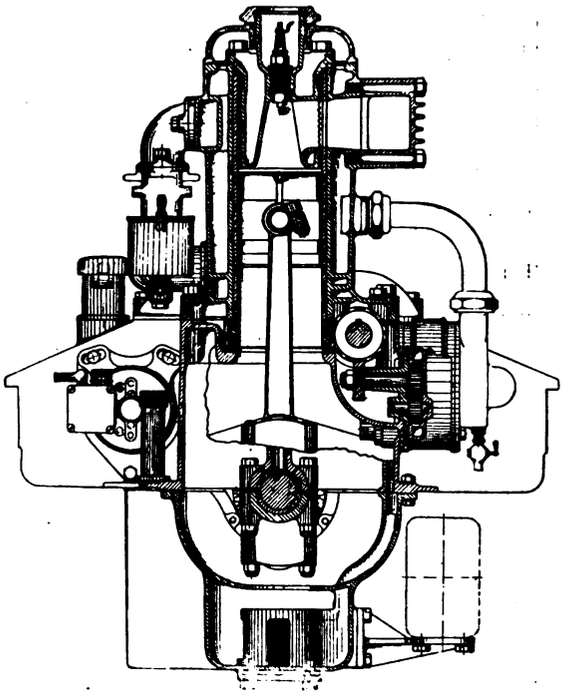
Trucks were grouped in convoys of 20, each group being in charge of an officer, and no group allowed to overtake another. Every truck was provided with its own two-wheel trailer, one of these being a workshop and another a kitchen, for each convoy. The truck with the workshop trailer was provided with ropes, pick, shovel, planks and long levers in order to give assistance to any vehicle which met with a road accident. Aboard the kitchen trailer meals were prepared for the entire personnel of the convoy, between 80 and 90 men, while the column was in motion. The supplies of food carried made the men independent of the country through which they were passing, but stages were so planned that several columns would reach the same town at night, when the men would be housed in the local barracks, in some public building, or, if necessary, billetted with the inhabitants.

Every truck carried its own gasoline and oil for the entire journey, and in addition a certain provision of gasoline to allow them to operate on reaching the Italian front. The distance which had to be provided for varied from a few hundred miles to over 1000, some of the troops starting from near the frontier, while others had to move from northern France into the heart of Italy. This huge movement of automobiles was responsible in a very large measure for the shortage of gasoline experienced by the public in many districts of France. The army had to take the whole of the reserve stocks found in their district, and for a time left civilians without a drop of gasoline.



Generally the freight space aboard the automobiles was made use of for goods rather than troops. Over such a long distance it was more economical to send infantry by train and let the automobile columns handle the material required by the artillery and the engineers. Much of the motor-hauled artillery was advantageously sent through by road, while the horse-drawn material was put on the railroad.

American Sleeve Valve Engine



AMONG the most interesting new engines seen at the recent New York automobile show was the American sleeve valve engine manufactured by the American Sleeve Valve Motor Co., Philadelphia. The dominant feature of the engine is a revolving cylindrical sleeve between the piston and cylinder wall which replaces the valve gear of the poppet valve type of engine. This sleeve, which is lubricated by oil films between the bearing surfaces, has no vertical movement whatever and in revolving passes the intake and exhaust ports in the cylinder at the proper time. The valve gear as a whole consists of the rotating sleeve, which is driven by a worm gear from the bottom of the sleeve. In this way the number of parts are considerably reduced as compared with that of the poppet type of valve gear.

One of the features of the valve gear is that the timing is not affected by the crankshaft speed, as it may be in the case of the poppet valve type, in which the loss of power at high speeds can be traced in a great number of instances to the inertia effects of the reciprocating parts of the valve

Digitized by Google

Side view of American sleeve valve engine showing sleeve gears and counter balanced crankshaft

Cross-sectional view of American sleeve valve engine

gear, which at high speeds will no longer follow the contour of the cams. On account of the rotating motion of the sleeve, it is worn equally by the piston, thus insuring a uniform piston clearance and also uniform compression.

The area of the intake and exhaust ports can be made large, and this fact makes possible very good scavenging action during the exhaust stroke, as the cylinder can be exhausted through an unobstructed port. The single sleeve also makes possible efficient cooling.

The engine is lubricated by a force feed system which is worked at constant pressure to guard against over-lubrication. The oil is carried to the upper part of the cylinders by means of helical grooves, which furnish the supply of oil for the oil film between the sleeve and the cylinder wall. The crankshaft is of the counterbalanced type and the pistons are light in weight. The crankcase and several other parts are made af aluminum.

The four-cylinder engine, which has a bore of 4 in. and a stroke of 5 in., develops a rather high horsepower for its displacement. The N. A. C. C. rating of the engine at a piston speed of 1000 ft. per min. is 25.6 hp., but the engine actually delivers 43.6 hp. at this piston speed. A test made on this engine by the manufacturer gave these results:

R.p.m.	B.hp.	R.p.m.	B.hp.
400.....	4.96	1600.....	50.88
600.....	10.20	2000.....	54.00
800.....	20.80	2400.....	56.88
1200.....	43.68		

From a production standpoint the engine represents practically straight machine work through the entire assembly.

Specifications for Class B Chassis Assemblies

(*Continued from page* 264)

manifold must be free from all leaks.

39. **Sprag**—All connections of cable must be secure. Raising and lowering mechanism shall operate properly.

40. All pin connections and pulleys must be well lubricated.

41. **Painting**—Chassis must be painted as per following specifications: The entire chassis must be thoroughly cleansed of all dirt, grease or oil, and covered with a coat of best quality rust-resisting metal primer.

It shall then be painted with two coats of best quality paint (olive-drab color), per sample submitted to this office for approval.

Each coat must be permitted to become thoroughly dry before applying following coat.

Purveyor to guarantee paint against checking, blistering or peeling for period of six months.

42. **Lubrication**—Before shipment each truck must be thoroughly lubricated. The engine, transmission, axle, steering gear, spring brackets and all grease cups, etc., must be filled to the proper level with approved lubricant.

43. **Preparation for Shipment**—Where rail shipment is required, all parts liable to rust must be coated with a heavy oil or dope.

44. Care must be taken that any parts liable to injury by weather or rough handling are protected in the proper manner.

45. The cooling system must be drained out to prevent damage by freezing. All gasoline must be drained out before shipment to prevent danger of fire.

46. The clutch must be blocked in the disengaged position to prevent the plates from sticking.

47. **Road Test**—Every chassis must go through a road test of at least fifty (50) miles. The last twenty (20) miles of this test must be made with a load of 7500 pounds, inclusive of the body but exclusive of passengers and equipment. At the completion of the road test all trucks shall be presented to the senior inspector or his designated representative for approval.

48. The inspector making this test must catch any deficiency in performance, cooling trouble, engine knocks, noisy gears, overheating axle and wheel bearings, defective brakes, play in universals, loose fits in splined shafts, governor action, clutch action, compression leaks at cylinder head gasket, spark plugs, valves or leaky piston rings, oil leaks in any part of engine, transmissions or rear axle, play in any part of steering arrangement, improper steering qualities, defects in control of truck, defects in spring action, defects in carburetion, unnecessary rattles in hood, floorboards, body, etc.

49. Governors to be checked for a speed of fourteen (14) miles per hour.

Modernizing Shipbuilding

PROBABLY the greatest problem that confronts our Government at the present time is that of quickly building a sufficient transport and cargo fleet to maintain a large army abroad. To speed up shipbuilding it was at one time proposed to build wooden cargo ships, but the impossibility of producing large wooden structures on the interchangeable plan and the insufficient strength of wood to withstand the heavy stresses of steam power and ocean waves made this plan impracticable and led to its abandonment.

Few ocean steamers had been built in the United States in recent times and there was therefore little equipment at hand for producing the special section steels used in shipbuilding. To have first produced such equipment would not only have meant delay, but would have put an unnecessary tax on the steel production of the country. The plan was therefore conceived of using structural shapes instead of marine sections, and though the ships still have to prove themselves, the fact that Lloyds, the big London marine insurance underwriting concern, has given them an A-1 rating is most encouraging.

In the production of these ships at certain points on the Atlantic seaboard we have an opposite to the methods employed in the production of the Ford car. Ford makes all his parts at one central plant, ships the parts to assembling plants distributed all over the country and has the cars assembled close to where they are to be placed in service. In the case of these cargo ships the parts are being produced in plants scattered all over the country, some of them as much as 1000 miles apart, are shipped to the yard on the coast and there assembled.

No one familiar with modern manufacturing methods would have doubted the practicability of the scheme, though some conservatively minded shipbuilders are said to have cast derogatory remarks. In peace times the difficulty of finding a market for a large number of vessels of the same design would have been a great obstacle to the introduction of the plan into practice and would probably have rendered capital timid. Here the demand for the largest possible number of vessels was ready-made and there were no market uncertainties to worry about. The war will no doubt establish the entire feasibility of this method of producing ships, and once it has proven itself it will never be given up again. Henceforth ships even of the larger cargo type will be manufactured and not built.

Aid the Tax Officials!

LARGE industrial concerns can materially assist the Government by helping their employees with the Federal income tax. It is now time to make out the blanks, and all those earning more than $800 a year, unless exempted, are required to make a return.

Factories employing large numbers of unskilled men and foreigners will be well advised in marshalling these men and imparting to them the necessary information in a systematic and efficient manner. Thus it is quite possible for the factory to take care of from 200 to 500 men a day with a force of from five to ten clerks. In this way they can expeditiously care for thousands of people who would otherwise join the long lines waiting at the Government offices, thus adding to the confusion there.

It is a matter of duty to assist the Government in every way during these times, in order to make the task of carrying on the war as light as possible. The income tax affects such a large percentage of the population that it is bound to necessitate a vast amount of work to handle it properly. It is quite easy to see that a company employing thousands of workmen can do the Government a real service which would be highly appreciated.

About 30 per cent of the men connected with an average manufacturing establishment are liable under the income tax laws. A company employing 6000 men will have probably 2000 who must fill out blanks and turn in a report on their yearly earnings. It is quite easy to see that if these reports come in batches of 200 or more, accompanied by a check for the total amount from some large industrial concern, it is going to be a much simpler matter for officials to check them over than if each man came up to the desk to be questioned by inspectors who do not know the nature of their work nearly as

Digitized by Google

well as do the employers. The slight expense necessary to take care of this will be readily undertaken by manufacturers who wish to do a real patriotic service.

Labor Prospects

SEMI-SKILLED and unskilled labor is going to be in strong demand this coming summer, according to present indications. There are generally three phases through which the labor demand passes in industrial work. First, there is the design stage, when draftsmen and engineers are in great demand. During this stage the scope of the work is outlined and the details of the product itself are settled.

The second stage might be called that of the tool maker. During this period tool makers, die sinkers, tool designers and labor of the highest class must be utilized. These men are naturally very scarce, for they have to go through long years of training and must possess an innate ability for the work.

The third stage is that of production. It is then that labor is employed most extensively and the semi-skilled men come into their own. The men who actually operate the machinery and do the work which has been previously outlined and prepared for them are by far the largest in number. The mental creators come first, and finally the machine operators. The skilled tool makers and other specialists of that nature are the middle men and are a very vital connecting link.

We are at the present time in the middle stage in a great many of our war undertakings. This applies probably most exactly to the aviation program. The plans have been made and the creative period has been passed. Just now factories all over the country are being tooled up as rapidly as possible with the limited numbers of highly skilled men available. Soon we will be out of this period and into the third, or production stage. It is then that the great demand for production labor will make itself felt, and, therefore, although the semi-skilled labor market is easy at the present time, it will be different the coming summer, so that factories may well prepare now for a shortage in this direction.

Overhead Cam Development

IN the experimental laboratories and on the drafting boards of many of the automobile factories, as well as in the offices of consulting engineers throughout the country, they are busy with new developments of the overhead camshaft engine. In view of the practically universal employment of this type of drive for the non-rotary types of aviation engine, it is very probable that some interesting developments for commercial use are under way.

It has been freely prophesied that the aviation engine as developed by the war would leave its stamp on the future passenger car and racing power plant. It is not only likely to do this, but it is also quite sure to have its effect on truck engine development, as it is quite well known that certain companies are considering overhead camshaft types for commercial car use. The advantage, of course, is in the direction of simplicity, in that a number of valve actuating components are eliminated.

For the passenger car engine the greatest advantage is perhaps not the simplicity of the valve mechanism, but the possibility of securing a nearly ideal combustion chamber shape. If the inherent difficulties can be overcome in this type of construction, an engine which develops a higher output for a given piston displacement is sure to result. This is due to the reduction of superficial wall area as compared with combustion chamber capacity. It is a well-known fact that the minimum wall area as compared with cubical contents of the combustion chamber is secured when the latter is a hemisphere. It is quite possible with the overhead development to quite closely approach the hemisphere.

Lubrication of the overhead parts has really ceased to be a problem, because if this can be taken care of under the severe conditions accompanying aviation service it surely can be coped with successfully on a truck or passenger-car engine. When the matter is sifted to the bottom, it becomes more a matter of cost than anything else, and in view of the growing simplicity of the overhead constructions, it is quite natural to assume that the costs on this type are being brought within the bounds where production methods will render them commercial.

Standardization

DURING the past couple of years there has been much discussion of the subject of standardization, in the lay as well as in the technical press. Unfortunately the term has been used in a somewhat loose manner and many people seem to be in doubt as to what is really meant by it.

In some instances large manufacturing concerns have concentrated all their resources upon the production of a single machine or model and have called it standardization. This practice would be more correctly described as intense specilization.

Some concerns assemble vehicles from parts made by well-established firms in the parts industry and call this standardization. By making use of dictionary definitions they might elaborate a rather plausible justification for their practice, but if their argument were accepted there would be by this time a great number of standardized cars.

Recently we have heard much of standard ships and standard miltiary trucks, motor cycles, aircraft, etc. In the case of ships it is the introduction of interchangeable manufacturing methods and in the case of the trucks, motor cycles, etc., the decision of the Government to have only one design of vehicle for any particular purpose, instead of several.

Finally we have the standardization of engineering details as carried on by the S. A. E., the British Engineering Standards Committee, the A. S. M. E., the I. A. S. B., etc. Here it is partly a matter of specifications for materials and partly of joints and connections which when closely specified make it possible to use accessories and fittings of any make interchangeably.

From the above it will be seen that the word standardization is rather overworked these days.

Coal Curtailment to Makers Unlikely

Ten Days Given Committee Representing 90% of Industry to Discuss Proposal of Dr. Garfield

WASHINGTON, Jan. 25—The directors of the National Automobile Chamber of Commerce and of the Motor and Accessory Manufacturers' Association met here yesterday together with the Automobile Industries Committee and Dr. Garfield and E. M. Noyes of the Fuel Administration, to discuss a certain reduction in the allowance of coal to the automobile industry.

The Fuel Administration at first demanded a 25 per cent reduction in the coal allowance. Following discussion, however, it was decided to give the industry and the Fuel officials about 10 days' time in which to think the matter over and again meet. A committee was formed composed of W. C. Durant, president General Motors Corp.; John F. Dodge, of Dodge Brothers; John F. Willys, president Willys-Overland, Inc.; C. C. Hanch, Studebaker Corp.; C. H. Pelton, Maxwell Motor Car Co., and the members of the Automobile Industries Committee, which will meet in 10 days to again take up the problem with the Fuel Administration.

Practically 90 per cent of the automobile industry is represented in the members of this committee, hence it is almost certain that whatever arrangements are made will be agreeable to the entire industry, but the arrangements which will finally be made will be first submitted to every member of the industry for final approval.

Those present included A. S. Mott, Alfred Sloan, Jr., T. J. Wetzel, C. E. Thompson, W. C. Rutherford, E. H. Broadwell and Christian Girl of the M. A. M. A., Hugh Chalmers, Roy Chapin, John F. Dodge, J. Walter Drake, C. C. Hanch, W. C. Durant, Alvan Macauley, W. E. Metzger and Carl H. Pelton of the N. A. C. C., and Alfred Reeves, M. M. Bradley, A. W. Copland and John R. Lee, the last two members of the Automobile Industries Committee.

The conference at first appeared to be unfavorable to the industry, but discussions by Mr. Durant, Mr. Rutherford, Mr. Chalmers, Mr. Copland and Mr. Dodge had a considerable effect on Dr. Garfield.

It was pointed out to him that in the first place the automobile industry is already curtailed about 30 per cent in production, which means an existing curtailment of the use of coal to that extent. Secondly, that the automobile industry is already engaged in war work amounting to more than $600,000,000 and will undoubtedly become further engaged in the work, which will require the maintenance of the present organizations to insure against future Government needs, and that this could not be done if the industry is to suffer further curtailment by coal allowance reduction.

W. C. Durant, who is chairman of the committee, has called a meeting for early next week in New York at which the matter will be further thrashed out before being again taken before a joint session of the N. A. C. C. and M. A. M. A. directors and Dr. Garfield.

—

Garfield Exempts Airplane Plants

WASHINGTON, Jan. 30—The purpose of the recent order of the United States Fuel Administrator was to help and not delay the manufacture of essential war materials. Every manufacturer of aircraft is exempt from the provisions of the order pertaining to the use of fuel. This was made plain to-day in a telgram from Dr. Garfield to James Storrow, Fuel Administrator in New England. The telegram was as follows:

"Burgess Co., Marblehead, Mass., manufacturers of airplanes, and expressly exempt from the order of Jan. 17, state they have been refused coal by your office. The obvious purpose of the recent order is to help and not retard the manufacture of essential war materials. Producers of aircraft are to receive coal next after those mentioned in Section 1 of the order of Jan. 17 before all others."

—

Saxon Six Increased $60

DETROIT, Jan. 31—The Saxon Motor Car Co. will increase the factory price of its 6-cylinder touring model $60, beginning Feb. 10, making the new list price $995. The price of the 4-cylinder model has not been changed. The price of all closed cars remains the same.

—

Manning Is Splitdorf Sales Manager

NEWARK, N. J., Jan. 26—F. C. Manning, for many years associated with the electrical ignition business of the country, has been appointed general sales manager of the Splitdorf Electrical Co. with headquarters at the main office. Manning will retain his presidency of the Sumter Electrical Co., a subsidiary of the Splitdorf Co. located in Chicago.

Extend Return Load Plan

Massachusetts, New York and Pennsylvania to Establish Central Trucking Bureaus

NEW YORK, Jan. 30—Proper return load facilities and an organization to carry out such work in Pennsylvania, Massachusetts and New York, as well as Connecticut, where it is now being done, are in sight. At a meeting of representatives of the State Councils of National Defense for these states yesterday it was decided to report back favorably to these respective councils that such work be taken up and pushed to conclusion as a war measure. The plan contemplates the establishment of central bureaus where truck drivers may report and be assigned return loads instead of returning to the point of departure with their trucks empty. The meeting yesterday was attended by John S. Cravens, W. S. Conning, George H. Pride and several others interested in the movement.

—

To Stimulate Drive-Aways

MILWAUKEE, Jan. 30—Wisconsin proposes to permit motor cars and trucks to be run over the highways of the state without a license when in transit from the manufacturer to the dealer. This is the one important change which is scheduled to come before the state legislature which convenes Feb. 19. This bill for the repeal of the licensing law in these special cases will operate to stimulate truck and car drive-aways and in this way will help to relieve freight congestion.

—

Move Aircraft Production Section to Cleveland

WASHINGTON, Jan. 30—The Production Section of the Signal Corps will remove its headquarters to Cleveland. This is being done in order the better to speed up aircraft production. The move will place those at the head of aircraft work virtually in the center of the manufacturing district.

—

Standard Parts Dividend

DETROIT, Jan. 30—The standard Parts Co. has declared a dividend of 1½ per cent on common stock payable Feb. 15 to stock of record, Feb. 1. This is the first dividend declared on common stock. The company was formed in December, 1916.

Automotive Industries

State War Money to Open Roads

Industrial Sections in Michigan To Be Put in Touch by Direct Trunk Lines

DETROIT, Jan. 26—Motor trucks and cars will be made independent of railway blockades according to the plan adopted by automobile manufacturers in conjunction with the county commissioners and the Michigan War Preparedness Board. Furthermore, the industrial centers of Michigan will not again be cut off from the rest of the country by railway tie-ups and embargoes.

Motor car manufacturers of Michigan are preparing now to meet the situation which may arise, preventing any further rail shipments of automobiles or motor trucks. Winter and summer drive-aways will be operated on a systematic basis with the co-operation of state and county authorities.

At a meeting held here yesterday and presided over by State Highway Commissioner Frank Rogers the main trunk lines to be kept open all year around were designated, and provision was made to meet the expenses of maintenance. Under present arrangements the state will pay at least half of the cost of maintaining the through roads, while the county funds will take care of the balance. Attorney General Groesbeck stated that the Michigan war preparedness board will finance the project out of its $5,000,000 fund.

Representatives of the large automobile factories throughout the state, such as the Olds Motor Works, Buick Motor Co., and other large concerns from outside of Detroit, as well as prominent companies in the city, such as Dodge Brothers and the Cadillac Motor Car Co., together with the Oakland company of Pontiac, were present and pointed out the great importance of these roads to the future of the industries in this state. The two heavy snows which have made travel impossible through this state during the last three weeks, have forced makers to abandon drive-aways and hence to stop shipments altogether. It is assured that co-operation between the manufacturers themselves, as well as on the part of the state and county authorities, will result in opening for traffic roads that would be otherwise impassable.

The highways concerned opened up the interior of Michigan to cities in communication with Detroit and Toledo, as well as to Chicago and points west. Five roads were proposed to receive immediate attention. They are as follows:

From Alma to Saginaw, Flint, Fenton, Holly, New Hudson, Detroit, Monroe and Toledo; following the Grand River west from New Hudson to Lansing, by way of Howell; one road to Chicago, by way of Charlotte, Battle Creek and Kalamazoo, another to Grand Rapids, via Ionia and Lowell, and another from Flint to Port Huron, via Lapeer, Emlay City and Capac.

Among those present at the meeting were: P. L. Emerson, sales manager Olds Motor Works, Lansing; Edmund C. Shields, Olds Motor Works, Lansing; Frank J. York, Cleveland Tractor Co., Detroit; Frank F. Rogers, State Highway Commissioner, Lansing; Edward N. Hines, Chairman Board County Road Commissioners, Wayne Co., Detroit; John J. Cox, Engineer for Eastern Washtenaw Good Roads, District of Washtenaw Co., Ann Arbor; Alex J. Groesbeck, Attorney-General, Detroit; E. C. Howard, general sales manager Cadillac Motor Car Co; W. M. Hogle, Dodge Brothers, district representative; Leonard Freeman, Flint; Flint Board of Commerce, H. S. Earle, Detroit; W. H. Masten, Oakland Motor Car Co., Pontiac; E. T. Strong, general sales manager Buick Motor Co., Flint.

—

Government Control for Gasoline

WASHINGTON, Jan. 30—President Wilson will within two weeks issue a proclamation taking over to government control fuel oil and gasoline. This action, which was forecast some time ago when L. Requa was appointed oil director, is considered imperative in order that supplies may be rushed to the industries needing them for the completion of war work. This does not mean that there will be any restriction placed on the use of gasoline for cars or trucks, for the reason that there is no shortage at present. On the contrary, the country is now producing far more gasoline than it can use. L. Requa will have charge of and make necessary provision for supplying those industries greatest in need of oil products and will curtail those whose needs are not so urgent.

—

Garfield Exempts Cars and Trucks

WASHINGTON, D. C., Jan. 25—The United States Fuel Administration has issued a statement to the effect that there is nothing in the order of Jan. 17 which called for the maintenance of heatless days to prevent the operation of automobiles, motor vehicles of all classes being considered as coming under the head of public utilities. In keeping with this ruling garages have been exempted also. This statement clarifies the situation and was made particularly in regard to the use of trucks operated in the movement in freight.

—

Senate Hears Aircraft Plans

WASHINGTON, Jan. 30—The Senate Military Affairs Committee will hear aircraft experts on the Aircraft Production Board and in the Signal Corps in executive sessions during the rest of this week. All of the details of airplane plans will be discussed in secret.

Won't Place Industry on Losing Basis

Garfield Tells Makers' Conference He Has No Such Intention

WASHINGTON, D. C., Jan. 28—Washington is alive with events vital to the automotive industry this week. Fuel, labor, standardized use of the Liberty trucks and other important problems have arisen.

Coal Curtailment Proposed

The chief event of the week was the meeting last Thursday of the Fuel Administration with representatives of about 90 per cent of the automobile industry. Dr. Garfield came to this meeting with the firm purpose of directing an immediate curtailment of 25 per cent in the use of coal with further plans for additional curtailment to a basis to be determined by the essential character of the industry.

He learned, as he himself stated at the meeting, that the automobile industry is really one that cannot be classed with any other in the country; that it is already engaged in almost a billion dollars' worth of war work outside of manufacturing passenger cars and trucks for the Government, and that since it contemplates taking on considerable more war work it must keep its organization intact.

Must Maintain Organizations

This, he conceded, could not be done if the industry had to curtail its present activities. In view of the fact that the industry is already curtailed 30 per cent by business conditions, he suggested that the matter be given consideration for several days, and that the committee appointed last Thursday make new recommendations at the coming meeting.

It is quite likely that committee will recommend a curtailment of coal allowance for the entire industry of 5 or 10 per cent. This curtailment can be overcome by the use of substitutes and more efficient methods, and it is thought most diplomatic and wise by members of the industry in Washington that some slight curtailment such as the one suggested be recommended.

Another Labor Hysteria

Last week witnessed publication throughout the country of news items to the effect that 250,000 workmen are needed immediately for the ship yards. This created another labor-shortage hys-

Digitized by Google

teria and is worrying many employers. The report is untrue.

It was given out by a member of the Shipping Board without qualification that this number of men would be needed in the future, which would be nearer the actual fact.

The Department of Labor stated to-day that commencing in the spring it will have to make a drive for ship-yard workers. It anticipates now that about 360,000 workers will be needed by Aug. 1, of which 220,000 will be skilled and semi-skilled. It plans to utilize the Public Service Reserve to enroll these workers voluntarily in the meantime. By this method it will know where to locate the men required and employers will know which men they are likely to lose.

The present hysteria about labor shortage is caused in the main by various shipbuilders throughout the country who anticipate that they will have to break contracts with the Government owing to the slowness in erecting plants and securing material, and who hope by their demands for workers to have an alibi later for the broken contracts.

Philadelphia ship yards, for example, are calling for 7000 men, and the Department of Labor states it could not really at this time place 20 men. The Department of Labor stated to-day that it could not even place 15,000 skilled and unskilled workers in all of the shipyards of the nation at this time, much less 250,000.

A most important decision by the Department of Labor to-day was to the effect that it does not expect to take any important number of workers from the automobile manufacturing industry, but anticipates that it will draw the kind of machinists and other skilled workers that it requires from the automobile repair and garage industry.

Figures on hand now show that about 31,000 inside machinists and 18,000 outside machinists will be required by Aug. 1 by the shipyards. Half of these, or about 24,000 men, the Department of Labor hopes to secure from the automobile repairshops and garages in the United States. It realizes that with the exception of a very few workers in the automobile manufacturing plants, such as tool makers, that there are a few all around machinists that it could use in ship-building.

The general staff of the War Department has recently made the very interesting and important decision to the effect that all departments of the War Department must use only the class B, class A and class AA standardized war trucks after July 1. This means the standardized use of standardized trucks. It eliminates the present system whereby each corps or division has its own kind of trucks together with the separate maintenance establishments, separate armies of repair men, separate stock of repair parts, etc. It is a movement toward actual co-ordination of this branch of the service.

The appointment of E. R. Stettinius as Surveyor General of supplies for the

80 Missouri Makers Discuss Safety

Plan to Reduce Accidents and Improve Traffic Laws at Council Meeting

KANSAS CITY, Jan. 22—Four hundred and twenty owners, managers, foremen and workmen of Kansas City establishments gathered around tables at the annual "get-together" meeting of the Local Safety Council the evening of Jan. 19, provided a striking indication of the way employer and employee are earnestly co-operating in these plants to maintain a high degree of efficiency in production during the war.

The owners and managers had been holding monthly meetings at noon, and the workmen had been holding monthly meetings in the evening for more than a year; and the Jan. 19 dinner was the culmination of their mutual ideals, separately worked out, for co-operation in the prevention of accidents and the maintenance of production.

The motto of the meeting—decided upon independently by the managers and by the workmen—was "All Together for Safety." The tone of the meeting was largely patriotic, the speakers emphasizing the service to country of the workmen who are faithful on their jobs in keeping industry going, and especially those who help prevent temporary slowing up by preventing accidents. The chief speakers were R. C. Richards, chairman of the central safety committee of the Chicago & Northwestern Railway; Isaiah Hale, commissioner of safety of the Santa Fe, and Dr. W. H. Coon, health director of Kansas City, Mo, for several years in charge of factory inspection for the Massachusetts State Board of Health. Officials of the Chamber of Commerce of Kansas City, Mo., and Kansas City, Kan., expressed the purpose to provide co-operation by those bodies in the objects of the Safety Council—the firms represented being located in Kansas and in Missouri. There were also short talks by foremen and workmen, who gave their views on the safety movement, and told why the foremen and workmen were interested in preventing accidents and in maintaining the highest efficiency in their own work and that of their fellow workmen.

There were 80 plants represented at the dinner. The large majority of diners were employees, though one or more owners or managers sat at each table, and the mixing of the plate-cards had effected the intermingling of the men, so that each table had men from various plants. The tickets to the dinner, $1.50 each, were paid for by the firms.

A sixth of the guests were men from plants not members of the National Safety Council.

E. G. Trimble, president of the local safety council and for several years a director of the national council, declared that this meeting was the most significant gathering on the subject of safety ever held in America, an opinion endorsed by other men present of national prominence.

The Foremen's Round Table, consisting of workmen from industrial plants, holds monthly meetings at the Chamber of Commerce rooms, where they discuss ways to make plant work safe, to educate workmen in safe practices, to improve the efficiency of the men and women for their own benefit and that of the plant.

Following are a few examples of the activities of the local Safety Council and of the round table:

(1) The Safety Council has taken up such subjects as traffic regulations; co-operative work to reduce accidents on the streets, especially as between the street railway and truck owners; education in safety of school children; interchange of information among managers on organization of safety committees in plants, and encouragement of suggestions as to hazards; discussion of ways to handle welfare work.

(2) The Foremen's Round Table gets down to bedrock on such subjects as guards for emery wheels, checking out of supplies (with special reference to inspection for safety) from stock rooms; inspection of plants for fire hazards; fire drills; handling of workmen who jeer at safety notices; education of workmen in use of safety devices; care of health as a means to improved efficiency and earning power; rules to truck and motor car drivers for the avoidance of collisions; equipment of freight elevators for safety.

New Regulations for U. S. Exports

War Trade Board Devises New Export Application Form—In Effect Feb. 1

WASHINGTON, D. C., Jan. 25—After Feb. 1 the War Trade Board will place in operation a number of new regulations regarding exports. A new export application form will be used, superseding all previous forms. It has been designed to avoid the necessity of shippers keeping various forms on file. The form, which will be known as Form X, calls for an answer to all questions, but the board, recognizing that it will not always be possible for shippers to furnish the information demanded, will be satisfied with as many answers as can be made. If the information furnished by the shipper is not sufficiently complete to enable the Bureau of Exports to act it will be returned with a request for more data.

Exporters who have at any time applied to the Bureau of Exports for export licenses are on the mailing list for the Journal of the War Trade Board, and are presumed to know of the change of forms. Neither failure on the part of the applicant, states the board, to take reasonable precaution as to the distribution of goods, nor the granting of an export license based upon the statements made in the application will relieve the consignor from any responsibility to which he may be liable for affording aid or comfort to the enemy.

An attempt to export a commodity differing in any way from that for which license has been granted subjects the exporter to the penalty of the law. If there is reasonable cause to believe that the exportation described in the Form X involves trading directly or indirectly with an enemy or ally of an enemy or with a person acting in behalf of or for the benefit of an enemy or ally of enemy as defined in the Trading With the Enemy Act, a separate application for license to so trade must be made.

—

Australian Import Extension Restricted

NEW YORK, Jan. 29—The three months' extension granted American manufacturers for the shipment of automobile bodies to Australia applies only to products which were on order August 10, 1917. At first it was thought there were no restrictions to the extension, but it appears that this is not entirely correct.

—

Ohio to Have War Roads Convention

COLUMBUS, OHIO, Jan. 26—Three state organizations all having to do with the highway problem in its several phases will merge their activities this year in the Ohio War Roads Convention to be held in Columbus, Jan. 30, 31 and Feb. 1. The associations are the Ohio Good Roads Federation, the Ohio Engineering Society and the County Commissioners' association. Co-operating with all is the state highway department.

The arrangements are under the direction of a committee with state highway commissioner Clinton Cowen as chairman, assisted by president D. S. Humphrey and secretary Walter A. Alsdorf of the Ohio Good Roads Federation; president A. R. Taylor and secretary John Laylin of the Ohio Engineering Society and president C. M. Hunt and secretary Richard Sinclair of the County Commissioners' association.

—

Packard Prices Increased

DETROIT, Jan. 26—Beginning March 1, the Packard Motor Car Co. will increase the factory prices of all the 3-35 models $200, and the 3-25 models $250. The price change is on the chassis only, all styles of bodies advancing the same amount. The prices follow:

Model 3-25 (128-in. wheelbase)

Model	New Price	Old Price
Roadster	$3950	$3700
5-pass. touring	3950	3700
7-pass. touring	3950	3700
Sedan	5650	5400
Limousine	5500	5250
Landaulet	5550	5300

Model 3-35 (134-in. wheelbase)

7-pass. touring	$4300	$4100
Sedan	6000	5800
Limousine	5850	5650
Landaulet	5900	5700

On account of freight conditions, the company will use the driveaway plan of getting cars to their destinations, and as many as possible will be driven from the factory.

—

Republic Advances Prices

ALMA, MICH., Jan. 26—The Republic Motor Truck Co. has increased the price of its models according to the following schedule, all prices being quoted in single units or in fleets, f.o.b. Alma, Mich.:

	Old Price	New Price
¾-ton (9 enroute)	$895	$995
1-ton (sold out)	1195	1295
1½-ton (6 enroute)	1550	1650
2-ton (14 enroute)	1885	1975
3½-ton (sold out)	2750	2950
5-ton (2 enroute)	4250	4500

Recently a new time schedule has been placed in effect. Both the offices and the plant closed on noon Saturday, the total time being made up by working one-half hour longer at noon. Formerly the noon period was from 11:30 until 1 o'clock. Now it lasts from 12 until 1. Otherwise the opening and closing hours remain the same.

—

Reiss to Distribute Carlisle Tires

NEW YORK, Jan. 28—Charles E. Reiss, Hupmobile distributer, has become wholesale distributer for the Carlisle Cord Tire Co., and will trade as the Carlisle Cord Tire Sales Co. The new company, which is not incorporated, will function as the wholesale distributer for the Carlisle company in a large part of the Eastern territory, including New York City and parts of Pennsylvania, New Jersey and Connecticut. The acquisition of the tire business will not in any way interfere with Reiss's Hupmobile interests or business.

1917 Gasoline Price Steady

Less Than 5 Per Cent Increase —Cost of Crude Oil Advances 25 Per Cent

NEW YORK, Jan. 26—While crude oil prices have advanced 25 per cent over last year's figures on the important grades, present gasoline quotations show less than a 5 per cent increase. A year ago gasoline sold for 23 cents a gallon, tank wagon basis, in New York. The present price is 24 cents. During the same time the price in Boston has varied only from 24 to 25 cents a gallon. In addition to the higher cost of crude oil, refiners have had to contend with increased labor charges and cost of materials, and the stability in the price of gasoline is attributed to the manufacturers' desire to keep it as low as possible, and the fact that they have advanced the price of other refined oils, such as kerosene and lubricating oils, in preference to gasoline.

Prices, tank wagon basis, in important cities, follow:

City	Current Price	Last Year's Price
Baltimore	22	22
Boston	25	24
Charleston	24.5	25.5
Chicago	21	19
Cincinnati	24	23
Dallas	26	22
Denver	24	23
Houston	26	23
Kansas City	20.3	18.9
Minneapolis	22	20
New York	24	23
Norfolk	22.5	22.5
New Orleans	22.5	22.5
Oklahoma City	25	23
Philadelphia	24.3	23
Pittsburgh	26	23
Richmond	22.5	22.5
St. Louis	20.4	18.4
San Antonio	26	22
Wilmington	24.3	23

—

Fuel Administrators Plan Zone Distribution

KANSAS CITY, Jan. 26—Fuel administrators of Kansas, Missouri, Oklahoma, Arkansas, Nebraska and Iowa held a conference in Kansas City Jan. 21, especially to discuss the proposal to appoint distributers by zones, and to perfect the co-operative arrangements for supplying coal to these states. They agreed that the season is too far gone for zone distributers to be of much avail in this district now. Most of the administrators are urging that operators make a reduction in price of coal at the mine starting with April, such reduction to be passed on to ultimate consumers who buy early (but to be to the advantage of the dealer who stocks and holds) in order that as much coal as possible may be placed this summer.

So far, no state administrator in this group has issued orders for the suspension of any manufacturing enterprises, or its curtailment, with two exceptions.

Digitized by Google

In Kansas, Emerson Carey passed along the federal order for the curtailment of straw board factory work; and in Missouri, Wallace Crossley has included breweries in his general order for the closing of saloons and amusements Mondays and Tuesdays. In Missouri, there are restrictions on the use of lights. Office buildings and stores, except those selling food, must be closed at 7 p.m. All lights in the downtown section, except enough to show the way must be turned out, and banquets, theaters, etc., closed at 10 p.m.

—

Trucks to Relieve Freight Congestion

MILWAUKEE, Jan. 28—The transportation division of the Milwaukee Association of Commerce is making an exhaustive investigation of the feasibility of motor truck freight service between Milwaukee, Chicago, and intermediate points, with a view to relieving congested railroad traffic. Frank Barry, traffic manager of the association, already has urged Milwaukee shippers to make wider use of trucks within the city, and between Milwaukee and nearby points, and the results are so favorable that it is believed likely that a system of motor transport over the longer distance between Milwaukee and Chicago, 90 miles, can profitably be instituted.

—

Morrow to Control Coal

WASHINGTON, D. C., Jan. 25—J. D. A. Morrow, secretary of the National Coal Association, has been appointed manager of apportionment and distribution of the fuel administration, and will act as first lieutenant to Dr. Garfield in this work, with practically full control of the nation's coal supply. This means that the supply of fuel to the nation is now under the direction of a man who has been associated with the bituminous coal mining industry.

—

Dale Made Sales Manager of King

DETROIT, Jan. 30—A. G. Dale has been appointed Western sales manager of the King Motor Car Co.

—

Continental Earns $1,396,814

DETROIT, Jan. 30—The Continental Motors Corp. reports net earnings of $1,396,814.17 for the fiscal year ending Oct. 31, 1917, which actually covers only nine and a quarter months of the corporation's business earnings before $24,000 excess profits were deducted. Income tax, depreciation and interest amounted to $2,052,068.12. Sales during this period show an increase of 32 per cent over the preceding year and operative orders on the books as of Oct. 31 totaled $17,361,000. After deducting cancellations at the close of the fiscal year, there were outstanding 35,000 shares of preferred stock of $100 par value and 1,451,858 shares of common of $10 par value. There were 3467 stockholders whose holdings averaged twenty-four shares of preferred and 759 of common. Within the past year additions to the plant amounted to $1,148,404.75, including fitting the plant for government work.

Goodyear Stock for Dealers

$25,000,000 Second Preferred Will Be Sold Only To Agents and Users

AKRON, O., Jan. 26—The Goodyear Tire & Rubber Co. has authorized an issue of $25,000,000 second preferred stock which is to be sold, not to the general public through stock brokers, but to Goodyear users through the service station dealers and to Goodyear dealers themselves. Instead of a commission to a brokerage firm, the company will pay each dealer $2 for every share sold by him. Only $15,000,000 of the stock will be issued at present, the remainder to be held in the treasury and sold under carefully drawn restrictions. The issue is in shares of $100 par value, bearing 8 per cent interest. They are cumulative and non-assessable, and must be bought back by the company within 10 years at the rate of not less than 10 per cent a year.

The Goodyear company believes that by this unusual plan its dealers will have an opportunity, not only to make a personal investment, but to cement the relations of dealers with their customers. The present war conditions, which have caused the increase in price of raw materials, and the prospects of a still further increase, necessitated the additional financing. The company already has $25,000,000 common stock, of which $21,000,000 is outstanding, and $25,000,000 first preferred, of which $23,000,000 is outstanding.

—

Slight Increase in Iron Mined

WASHINGTON, D. C., Jan. 25—Iron ore mined in the United States in 1917 amounted to 75,324,000 gross tons, compared with 75,167,672 tons in 1916, an increase of .02 per cent. Shipments from mines in 1917 were valued at $236,178,000 as compared with shipments valued at $181,902,277 in 1916. The stocks of iron ore at the mines have decreased from 10,876,352 gross tons in 1916 to 10,560,000 tons in 1917. Imports of iron ore for 11 months ending Nov. 30, 1917, amounted to 913,500 gross tons, as compared with 1,325,736 tons for the full year of 1916.

—

Government Takes Ford Washington Branch

WASHINGTON, Jan. 30—The Quartermaster Corps of the United States Army has taken over the 8-story Washington branch building of the Ford Motor Co. The building was turned over to-day. The Ford company will open a new branch and service station as soon as a suitable location can be found.

—

Ford to Make Own Carbureters
